LIST OF ILLUSTRATIONS.

SPECIAL PLATES.

	PAGE
Bone Clip for the Operative Treatment of Fractures (Joseph E. Adams) ... facing	259
Cancer of the Breast (Sir G. Lenthal Cheatle) ... facing	870
Carrelli Method of Perirenal Inflation (F. Hernaman-Johnson) ... facing	90
Death from Cancer, Unusual Case of (E. A. Linell) ... facing	871
Diaphragmatic Hernia (George J. Langley) ... facing	91
Dissecting Aneurysm of the Aorta (Sir Henry Davy and Mabel Gates) ... facing	467
Foreign Bodies in the Gastro-intestinal Tract in Appendicitis (William C. Allardice) ... facing	467
Fracture of the End Phalanx of Finger (J. N. Laird) ... facing	91
Hereditary Polydactylism (R. F. Young) ... facing	91
Oral Sepsis in Relation to General Disease (J. M. Ackland) ... facing	871
Pneumothorax in a Boy aged 7 (William B. Martin and Robert Knox) ... facing	467
Psychography: Three Cases illustrating the Value of (Clifford Morson and H. P. Winsburg White) ... facing	258
(Frank Kidd) ... facing	750, 751
Reproductive Organs in Relation to Mental Disorders (Sir F. W. Mott) ... facing	466
Suture of Ruptured Left Dome of Diaphragm (C. Jennings Marshall) ... facing	871
Traumatic Arterio-venous Aneurysm (George G. Farquhar) ... facing	467

ILLUSTRATIONS IN THE TEXT.

After-treatment of Acute Abdominal Disease (H. W. L. Molesworth)...	220
Aluminium Throat Swabs (Lachlan Grant) ...	434
Amputations at the Shoulder and at the Hip (H. Littlewood) ...	381
Arthritis Deformans, Surgical Treatment of (Harry Platt)...	673
Aspirator, a Simple ...	109
Bacteria, the Digestibility of (C. E. Dukes) ...	430
Bone Clip for the Operative Treatment of Fractures (Joseph E. Adams) ..	259

Choroid Plexus and Psammomas (Sir John Bland-Sutton)...	213
Death from Cancer, Unusual Case of (E. A. Linell) ...	872
Ethereal Extract of Strawberries for Treatment of Sprue (Aldo Castellani and K. C. Browning) ...	718
Fats in Relation to Goitre (Lieut.-Col. Robert McCarrison)...	179
Gairdner, Sir William ...	21
Glasgow and District, Views of ...	21, 242, 649, 883
Haemorrhoids Treated by Suture, Instrument for ...	64
Heart Symptoms, Nature and Significance of (Sir James Mackenzie) ...	505, 552
Influenza Epidemics in Schools, Restriction of (A. I. Simer and John W. H. Eyre) ...	433
Intratracheal Medication ...	149
Non-rheumatic Aortic Stenosis (W. Gordon) ...	836
Obscure Intestinal Colic (H. Tyrrell Gray) ...	254
Pain, Clinical Aspects of (Henry Head) ...	2
Prostatic Enlargement in Old Age, Nature and Cause of (Kenneth M. Walker) ...	297
Puerperal Infection, a Method of Preventing (F. H. Whyte) ...	638
Radium Applicator Forceps ...	842
Radium Therapy (Robert Knox) ...	633
Reproductive Organs and Mental Disorders (Sir F. W. Mott) ...	463
Rhodesian Skull ...	198
Rivers, W. H. R. ...	977
Skull (?) of Sir Thomas Browne ...	726
Slipping Peroneal Tendons Treated by Kelly's Operation (D. W. Hume) ...	600
Spasmodic Stricture of the Uterus (M. A. Dobbin Crawford) ...	136
Specific Sensitiveness and Anaphylaxis (H. H. Dale) ...	45
Stomach and Duodenum, Secretion into (T. Izod Bennett and E. C. Dodds) ...	9
Synovitis of the Knee-Joint, Chronic (Captain G. Gelston Atkins) ...	948
Trichotillomania due to Threadworms (Henry C. Semon) ...	641
Urethroscope Tube for the Posterior Urethra ...	356
Vaginal Retractor, a Self-retaining ...	64
Valentine Mott's Aneurysm Needle (Alban H. G. Doran) ...	640

- Anti-anaphylaxis (Fernand Vidal), 854
Antidysentery serum in treatment of asylum
dysentery (P. Lornie and D. Ellis Jones), 949
(O)
Antigen, tuberculous egg, prepared, 109
Antigua, parasitology and clinical aspects of
malaria in (W. M. McDonald), 597 (O)
Antimony, butter of, case of poisoning by
(William Bell), 917 (O)
Antimony in leprosy (G. H. Wildish), 55 (O)—Note
on, 939
Antimony in syphilis (F. G. Cawston), 266—Note
on, 939
Antimony, tartarated, rectal administration of
in bilharziasis (H. F. Wilson), 137 (O)
Antimony, therapeutic uses of, 296, 504
Antimony, a case of trypanosomiasis from West
Africa cured by (Sir Percy Bassett-Smith), 311
Antiseptic dyes, See Dyes
Antituberculous vaccination by the mouth, 613
Antivivisection Bill, a new (leading article), 528.
See also Animals and Cruelty
ANTONI, N., awarded the Lennmalm prize, 43
Aortic aneurysm, the recognition of (E. M.
Brockbank), 181 (O)—(C. H. Broomhead), 266—
Correspondence on, 246, 370, 454, 499, 540, 561
Aortic murmur (Thomas Lindsay), 759—Corre-
spondence on, 902, 1010
Aortic stenosis, non-rheumatic (W. Gordon), 836
Apothecaries' Society of London, discontinuance
of trading operations of, 861, 939, 1010
Appendicitis, acute, foreign bodies in the gastro-
intestinal tract in (William C. Allardice), 473
(O)
Appendicitis, acute gangrenous, simulated by
pneumococcal peritonitis (J. F. Roy), 347
Appendicitis, incipient acute, diagnosis of
(Robert M. Rowe), 226
Appendicitis, review of books on, 393
Appendix dyspepsia (R. J. M. Buchanan), 800
Appendix removed at operation subsequently
fixed and bisected in the longitudinal mesial
plane (E. Emrys-Roberts and H. A. Haig), 681
Approved societies. See Insurance and Pro-
fession

THE
British Medical Journal.

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

EPITOME

OF

Current Medical Literature.

JANUARY TO JUNE, 1922.

London :

PRINTED AND PUBLISHED AT THE OFFICE OF THE BRITISH MEDICAL ASSOCIATION,
429, STRAND, W.C.

INDEX TO THE EPITOME FOR VOLUME I, 1922.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Eye, Ophthalmia, and Vision, etc.

The Figures in this Index refer to the Number of the Paragraph, NOT the Page.

A.

ABER: Methyl violet in suppurating wounds, 63
abdominal arterio-sclerosis, 104
abdominal colic with porphyria, 476
abdominal disease, diagnosis of, 285
abdominal moles, congenital insufficiency of, 259
Abortion, frequency of in Germany, 121
Abortion, operative treatment of infection following, 560
Abortion and pelvic suppuration followed by tetanus, 120
ABRAMOWITZ: Phenolphthalein eruptions, 499
Abscess, ischio-rectal, etiology and treatment of, 159
Abscesses, cold: Treatment of, 339—Treated with injections of cod-liver oil, 191
Abscesses of liver, gas-containing, 359
accommodation, paralysis of, 573—Dne to arsenobenzol, 361
Acetyl-salicylic acid, local use of, 263
Acidosis and diathetic oedema, 277
Acridine dyes in dermatology, 8
Actinomycosis, human, 475
Actinomycosis of the tongue, 601
Actinomycosis and echinococcosis of the spine, 164
Adeno-fibroma of the breast showing malignant evolution, 73
Adenoid tissue, x-ray treatment of, 282
Adenoids, the palate in relation to, 110
Adenoids and tonsils operations, end-results of, 310
Adenoma of the corpus uteri, post-climacteric, 218
Adipose tissue in malignant disease, the fat of, 522
ADLER: Treatment of cervical carcinoma, 442
Adnexal disease, operative treatment of, 93
Adnexal inflammation, chronic, treatment of, 342
Adrenaline, intracardiac injections of in acute heart failure, 137
Adrenolind and shock, 540
ANNELLO, F.: Post-encephalitic blindness with minor lesion of fundus, 577
ALBRECHT: Thyroid extract in the vomiting of pregnancy, 318
ALBERTANIN: Tubercle bacilli in the blood, 299
ALBRECHT: Elimination of arsenphenamin and neo-arsphenamin in the urine, 271
Albumin in diabetes, the sparing action of fats on the destruction of, 269
Albuminuria, orthostatic, Struss's water test in, 154
ALCHER: Malarial neuritis, 100
ALMEYER: Mercurial tonsillitis, 9
Amputation treatment for chronic ulcers of the leg, 283
AMANN: Ammonium carbonate in erythema nodosum, 456
Amoebic dysentery. See Dysentery
Ammonium carbonate in erythema nodosum, 456
Ammonium chloride in treatment of infantile tetany, 357
Anaemia pernicious, significance of the haemoglobin, 520
Anaemia, post-influenza, iron in, 525
Anaesthesia, ethyl chloride, 114
Anaesthesia, general, danger of in cyclic vomiting, 534
Anaesthesia, local, Caesarean section under, 391
Anaesthesia, local, diagnostic exploitation of, 289
Anaesthesia, local, the secondary effects and sequelae in, 391
Anaphylactic shock, the antitryptic power of the blood in, 324
Anaphylactic symptoms of alimentary origin, treatment of, 54
ANNEBODIAN: Treatment of puerperal infection by douches of Dakin's fluid, 169
Aneurysms of peripheral arteries, mycotic embolic, 270
Aurina pectoris, diagnosis of, 156
Auricular, treatment of, 233
Anti-anaphylactic action of lipoids, 348
Antibodies, identity of, 25
Antibody content of the serum in phthisical patients, variations in, 610

Antimony in the treatment of leprosy and bydatid disease, 545
Antimony. See also Tartar emetic
Antiscurbic value of dried fruits, 328
Antiseptics, action of, and surface tension, 149, 298
Antistreptococcal serum. See Serum
Antisyphilitic treatment during pregnancy, importance of, 603
Antiveneral prophylaxis, experiments with, 17
APPERT: Indications for operation in cholelithiasis, 314
Aorta, thrombosis of, 428
Aortic disease in pregnancy, 584
APERT: Insufficiency of the soft palate, 389
Appendicitis chronic, infantilism in, 312
Appendicitis simulated by influenza, 464
Appendicitis, treatment of, 237
Appendix stump, treatment of, 485
ARCTAMBAULT: Complications of salvarsan treatment, 230
ARCHER: End-results of tonsils and adenoids operations, 310
ARCHIBALD: Tubercular leprosy, 152
ARMAND-DELLILE: Displacement of the trachea, 178—Variations in the antibody content of the serum in phthisical patients, 610
ARNOLD: Haemorrhagic osteomyelitis, 60
Arrhythmia perpetua, quinidine and digitalis in, 459
Arsenic, the fatal dose of, 203
Arsenical treatment of general paralysis, 458
Arsenobenzol causing paralysis of accommodation, 361
Arsphenamin and neo-arsphenamin in the urine, elimination of, 271
Arsphenamin, silver, 131. *See also* Salvarsan, silver
Arterial hypertension, treatment of, 505
Arteries, peripheral, mycotic embolic aneurysms of, 270
Arterio-sclerosis, abdominal, 104
Artery, epigastric, spontaneous rupture of, 261
Arthritis, chronic, sulphur injections in, 255
Arthritis, gonococcal, treated by intramuscular injections of synovial fluid, 87
Arthroplasty of knee-joint, 283
Artificial pneumothorax, 402
Ascariasis of the bile ducts, 569
Ascites in chronic malaria, 593
Asthma due to coostipation, 155
Asthma, saturnaline, 183
Asthma, treatment and pathology of, 232
Astria of the vagina, a rare cause of, 470
AUBERTIN: Thrombosis of the aorta, 423
AUBRY: Arseofocal treatment of general paralysis, 458
Auricular fibrillation, quinidine in, 56
Auto-haemotherapy in the treatment of dermatoses, clinical reactions in, 99

B.

Babinski's reflex, 350
Bacillary dysentery. See Dysentery
Bacilli, haemophilic, 612
Bacillus aerogenes capsulatus infection complicating typhoid fever, 251
Bacillus bacteriemia, fastiform, 496
B. diphtheriae. See Diphtheria bacilli
Bacillus, Pfeiffer's, differentiations of, 443
Bacillus, Pfeiffer's, and influenza, 401, 443
Bac. nusslii injury in, 258
BACKE: Menorrhagia treated by radium, 119—Fatalities from calumel injections, 304
Bacteria, metabolism of, 371
Bacterial flora of infants' throats, 400
Bacterial virulence in relation to vaccine production, 587
Bactericidal power of certain disinfectants and surface tension, 149, 298
Bacteriology of peridental tissues radiographically suggesting infection, 224
BAILLY: Experimental researches on diabetes insipidus, 613
BALSINGER: Treatment of gonococcal arthritis by intramuscular injections of synovial fluid, 87
BALZEN: Syphilis of the bronchi and lungs, 527

BANUS: Muscular tetanus, 201
BARR: Ptero-pulmonary fistulae, 433
BARNETT: Ascites in chronic malaria, 593
BARKMAN: Injury to the pituitary body by epidemic encephalitis, 503
BARNETT: Hydatid thrill, 109
BARRAQUER operation for cataract, 112
BARRÉ: Treatment of sciatica, 334
BARRINGER: Carcinoma of the prostate, 506
Basal metabolic rate, 225
Basic metabolism in exophthalmic goitre, 588
Baths, general carbon arc light in treatment of lupus, 409
BECLÈRE: X-ray treatment of uterine fibroids, 44
BEDFORD: The gold-sol test in mental disease, 295
BEDSON: The experimental production of purpura, 245
BEESON: Elimination of arsenphenamin and neo-arsphenamin in the urine, 271
BELL: The serological differentiation of some strains of *B. diphtheriae*, 147
BENARD: Complications of rubella, 228
BENTHIN: Perforation of uterus without destruction of ovum, 367
BERARD: Paralysis of the recurrent laryngeal nerve after thyroidectomy, 416
BERGHAUSEN: Silver arsenphenamin, 131
Beri-beri, treatment of, 1
BERLIN: Prellitis, 484
BERNER: The incidence of cancer in extreme old age, 136
BERNSTEIN: Dysentery in Vienna, 29
BERREITER: The frequency of malignant metastasis in myoma, 66
BERTER: Treatment of haemoptysis due to tuberculosis, 106
BERWICK: The bacteriology of peridental tissues radiographically suggesting infection, 224
BETH: The diagnosis of naemic conditions, 233
BEZANCON: Apparent increase of tubercle bacilli in sputum undergoing putrefaction, 541
BIGLOW: Yaws and syphilis, 346
BIGOR: Insufficiency of the soft palate, 389
Bile ducts, x-ray examination of, 358—Ascariasis in, 559
Bilharzia, treatment of, 180
Bilirubinemia in the newborn, 125
BINETTI: A new cancer-serum reaction, 422
BIONDO: Vitamins and immunity, 72
Bird-mite dermatitis, 130
BIRNBAUM: Venous ligature for puerperal pyemia, 90
Birth, five children at a, 569
Births during war time, 608
Bismuth and mercury, 52
Bismuth treatment of syphilis, 51
Bladder epithelium, desquamation of in scarlatina, 571
Bladder, hernia of, etiology of, 583
Bladder, treatment of spontaneous rupture of, 620
Bladder, syphilis of. See Syphilis
Blindness, post-encephalitic, without lesion of fundus, 577
BLUCH: Displacements of the trachea, 173—Epileptiform attacks in sero-fibrinous pleurisy, 570
BLOHMEN: Scabies norvegica, 3
Blood, antitryptic power of in anaphylactic shock, 323
Blood cells, red, in cancer, 297
Blood corpuscles, red, diameter of at different ages, 347
Blood culture in the diagnosis of typhoid fever, 172
Blood, effused, reinjection in, 183
Blood cross, relationship of to disease, 273
Blood in high blood pressure, vaso-constrictor substances in, 374
Blood pressure, high, with tachycardia, 425
Blood, pyrazinon test for, 562
Blood reaction in dyspnoea, 609
Blood in renal disease, indican in, 611
Blood, reinjection of after rupture of an extra-uterine pregnancy, 219
Blood in tetraethoxythane poisoning, 171
Blood, tubercle bacilli in, 229
BLOUNT: Bacterial flora of infants' throats, 400

- BLUM:** The antiphlogistic action of calcium salts, 146
- BOAS:** Importance of antisyphilitic treatment during pregnancy, 603
- BOCCARA:** Fox and Fordyce's disease, 31
- BORZ:** Synthetic medium for growing tubercle bacilli, 445
- BOISSIER-LACHON:** Treatment of erysipelas in the newborn, 207
- BONE GRAFTS:** From the tibia in cranioplasty, 35
- BONES:** Cancer and metastases in, 189
- BONNET:** The intradermal reaction in experimental tuberculosis, 491
- BONNIN:** Glomerular haemangioectases in the nephritis in typhoid fever, 70
- BOER:** Typhoid spondylitis, 140
- BOERX:** and potassium tartrate in treatment of ... hernia, 533
- BOISSE:** ... 157
- BOISSIER:** Marking-ink poisoning, 179
- BOISSE:** Synthetic medium for growing tubercle bacilli, 445
- BOUJIN:** Treatment of ringworm of the beard, 250
- BOUJIN:** Adenoma of the breast showing ... of the first metastases in a child, 338
- BRANNACHARI:** Cutaneous leishmaniasis, 544
- BRAIN:** extraction of foreign bodies from, 488
- BRAM:** Exophthalmic goitre and digitalis, 501
- BREAST:** massive hypertrophy of, 34
- BREMER:** Experimental researches on diabetes insipidus, 613
- BRENNER:** Perforated ulcers of the duodenum, 460
- BRISOTTO:** The pathogenesis of gastric ulcer, 415, 509
- BROOK:** ... See Ligament
- BROOK:** ... circumscribed, 32
- BROOK:** and ... syphilis of, 527—In typhoid fever in children, 548
- BROOK:** ... 80
- BROWN:** presentations, 538
- BROWN:** Plastic operations on the lip, 135—Relationship of *Treponema pallidum* to lymphoid tissues ... 232
- BROWN:** ... 232
- BROWN:** ... 333
- BROWN:** ... blood groups to disease, 275
- BROWN:** Non-operative treatment of ureteral calculi, 530
- BULL:** The relation of embolism in the limbs to heart disease, 303
- BURCHARD:** The slightness of the contagion of lupus vulgaris, 355
- BURNOWS:** Radiotherapy for cancer of the cervix, 490
- BUSACCA:** An intracutaneous reaction for tuberculosis of the skin, 199
- BUTLER:** Ovarian torsion, 91
- BUTTERFLY:** food in infancy, value of, 33
- C.**
- Caesarean section:** indications for, 21
- Caesarean section:** versus induction of labour, 341
- Caesarean section:** under local anaesthesia, 334
- Caesarean section:** vaginal, indications for, 537
- Caffeine:** morphine, and strychnine in labour, 144
- Calcium:** in salvarsan poisoning, 574
- Calcium chloride:** in treatment of diarrhoea in tuberculosis, 7
- Calcium chloride:** intravenous injection of in pulmonary tuberculosis, 77
- Calcium lactophosphate:** in cyclic vomiting, 383
- Calcium salts:** antiphlogistic action of, 146
- Calculi:** giant vesical, 333
- Calculus:** uterine, non-operative treatment of, 530
- Calculus:** urinary, 39
- CALDAROLA:** Differentiation of Pfeiffer's bacillus, 448
- CALIGATE:** Cutaneous leishmaniasis, 62
- Calomet:** a new technique for intramuscular injections of, 275
- Calomet injections:** fatalities from, 304
- CAMPBELL:** Composition of the urine, 71
- CAMPICHE:** Injuries to the semilunar cartilage, 284
- CANUS:** The pathology of diabetes insipidus, 543
- Cancer:** acquired resistance to, 497
- Cancer:** of cervix and chancres, differential diagnosis of, 517
- Cancer:** of cervix and pregnancy, 559
- Cancer:** of cervix, early diagnosis of, 118
- Cancer:** of cervix, inoperable, abdominal application of radium for, 195, 196
- Cancer:** of cervix, radium in, 94, 195, 196, 490, 491, 492
- Cancer:** of cervix, rate of growth of, 583
- Cancer:** of cervix, treatment of, 441, 442
- Cancer:** and chronic cystic mastitis, 36
- Cancer:** in extreme old age, the incidence of, 186
- Cancer:** of Fallopian tube, 467
- Cancer:** of gall bladder and cholelithiasis, 262
- Cancer:** hepatic, and echistosomiasis, 222
- Cancer:** of the jejunum, 529
- Cancer:** of lung, diagnosis of, 227
- Cancer:** and metastases in bones, 189
- Cancer:** mortality, 472
- Cancer:** of ovary, treatment of, 536
- Cancer:** of the prostate, 506
- Cancer:** of rectum, abdominal hysterectomy before removal of, 68
- Cancer:** of rectum, operation for, 410
- Cancer:** red blood cells in, 297
- Cancer:** serum reaction, a new, 422
- Cancer:** of the spine, 581
- Cancer:** tax, in mice, 321
- Cancer:** of the tongue, radium therapy in, 214
- Cancer:** of uterus, duration of life in, 294
- Cancer:** of uterus, end-results of treatment of, 606
- Cancer:** of pregnant uterus treated by radium, 266
- Cancer:** of vagina, end-results of treatment of, 606
- Cancer:** of vagina, primary, 315
- CANTANI:** Hilum tuberculois, 210
- Carbon:** are light baths in treatment of lupus, 409
- Carcinoma:** See Cancer
- Cardiac:** therapy, quinidine in, 175
- Cardio-tuberculous:** cirrhosis (Hutinel's disease), 14
- CARINI:** Treatment of prostatic hypertrophy, 438
- CARLWITZ:** Lupus treated with general carbon arc light baths, 409
- CARRIER:** The presence of *Leptospira icterohaemorrhagiae* in rats, 565
- CARTASO:** Pelvic varicocele, 197
- CARTAC:** the Barraquer operation for, 112
- CATERAS:** Cancer and metastases in bones, 189
- CATERAS:** elms, thrombophlebitis of, of dental origin, 41
- CAWSTON:** Antimony in the treatment of leprosy and hydatid disease, 545
- Cedar-wood:** oil in treatment of gonorrhoea, 34
- Cephale:** bruits in children, 150
- Cerebral:** hemiplegia, progressive, 549
- Cerebral:** injury and cranioplasty, 486
- Cerebral:** lesions after enuresan treatment, fatal, 354
- Cerebro-spinal:** fluid, the colloidal benzoin reaction in, 474
- Cerebro-spinal:** fluid, virulence of in genital herpes, 124
- Cervical:** gland. See Gland
- Cervical:** vertebrae. See Vertebrae
- CHARNICK:** Pandey's reaction for differential diagnosis between meningitis and meningism, 446
- Chancre:** and cervical cancer, differential diagnosis of, 517
- Chancre:** soft, 563
- CHANDRON:** Glomerular haemangioectasis in the nephritis of typhoid fever, 70
- CHARRIER:** Carcinoma of the jejunum, 529
- Chemical:** investigation of pregnancy toxemias, 535
- Chicken:** sarcoma. See Sarcoma
- CHIMICHIO:** Morphine, strychnine, and caffeine in labour, 144
- Child:** the nervous, 596
- Children:** fire at a birth, 369
- China:** malaria in, 352
- Chlorosis:** periodicity of the incidence of, 301
- CHMELAR:** Treatment and prophylaxis of puerperal fever, 268
- Cholelithiasis:** and carcinoma of the gall bladder, 262
- Cholera:** 590
- Cholera:** the mechanism of infection with, 498
- Cholera:** pathogenicity of, 72
- Cholera:** vaccine, living sonetized, 473
- Cholelithiasis:** indications for operation in, 314
- Chondritis:** post-typhoid, 187
- Chorion-epithelioma:** and hydatidiform mole, 604
- CHIGNOZZI:** Infantile in chronic appendicitis, 312
- Cinchonine:** and malaria, 204
- Circulation:** the intraocular, 558
- Circumcision:** followed by tuberculosis, 417
- Cirrhosis:** cardio-tuberculous (Hutinel's disease), 14
- CLARET:** Treatment of anaphylactic symptoms of alimentary origin, 54
- CLARK:** Epileptoid attacks in hypopituitarism, 307—Re-educational treatment of confirmed stammering, 523
- CLAPI:** Gonococci in the preputial folds, 605
- Club-foot:** congenital, treatment of, 83
- COAKLEY:** Haemorrhage during and after tonsillectomy, 185
- CODD:** Neuro-psychiatric examinations, 280
- CODD:** liver oil injections in treatment of cold abscesses, 191
- COLE:** Early diagnosis of pneumonia, 5
- Colectomy:** for chronic intestinal atresia, 556
- Colic:** abdominal, with porphyria, 476
- Colles's:** fracture followed by "spontaneous" rupture of the extensor longus pollicis tendon, 136
- Colles's:** fracture, statistics of, 576
- Colles's:** law, an explanation of, 317
- COLLIN:** Treatment of appendicitis, 237
- Colloid:** benzoin reaction in the cerebro spinal fluid, 474
- COLOMBINO:** Heliotherapy in gynaecological practice, 344
- Colon:** pelvic, x-ray examination of in gynaecological diagnosis, 365
- Colon:** post-operative ulceration of the, 599
- COMESATTI:** Malaria, 477
- Complement:** fixation reaction in tuberculosis, 226
- Conjunctivitis:** relation of to rainfall, 287
- Constipation:** causing asthma, 155
- Consumption:** See Tuberculosis
- CONY:** Statistics of Colles's fracture, 576
- COOMBS:** Streptococcal infections of the heart, 296
- COOPERMAN:** Ootitis fibrosa, 597
- Corpus:** luteum in diagnosis and therapeutics, 45
- Corpus:** uteri, post-climacteric adenoma of, 218
- COSACSE:** Syphilis of the bladder, 212
- COSERA:** The regional cuti-reaction, 125
- COSTANTINO:** Five children at a birth, 369
- COSTANTINI:** Tumours of the temporal lobe, 236
- COTTON:** Post-typhoid chondritis, 187
- COULON:** Synthetic method for growing tubercle bacilli, 445
- COVISA:** The Wassermann reaction, 98
- COZZOLINO:** Deficiency of fat soluble vitamins in rickets, 320
- Cranioplasty:** with bone grafts from the tibia, 35
- Cranioplasty:** and cerebral injury, 486
- Craniotabes:** and syphilitic rickets, 331
- CRISTX:** Diagnosis of cancer of the lung, 227
- CRILL:** Operations on the thyroid gland, 238
- CRON:** Obstetric uses of pituitary extract, 466
- Cruel:** ligaments of knee. See Knee
- CURRER:** Giant vesical calculi, 333
- CURCHOB:** Cardio-tuberculous cirrhosis (Hutinel's disease), 14
- CURRER:** The fat of adipose tissue in malignant disease, 522
- CURTIS:** Chronic inflammatory conditions of the Fallopian tubes, 18
- Cutaneous:** leishmaniasis, 62
- Cuti-reaction:** regional, 125
- Cyclic:** vomiting. See Vomiting
- Cyst:** hydatid, 363. See also Hydatid
- Cyst:** of pancreas treated by enucleation, 462
- Cystic:** kidney, bilateral, 463
- Cystic:** tumours of the uterus, 582
- Cysts:** of ovary, perforating haemorrhagic, 117
- D.**
- DAELS:** A method of intrapelvic radium therapy, 143
- Dakin's:** fluid, douches of in treatment of puerperal infection, 169
- DALLA:** VEDOVA: The treatment of tuberculous spondylitis, 240
- DANOSCHAT:** Congenital perineal ectopia of the testis, 38
- DANZIN:** Diagnosis of angina pectoris, 156
- DA SILVA:** The presence of *Leptospira icterohaemorrhagiae* in rats, 565
- DAVID:** Births during war time, 608
- DAVID:** Experimental epidemic encephalitis in rabbits, 26
- DAVIES:** Endocrine disorder and mental disease, 453
- DAVIS:** Exudative erythema, 194
- DAVIS:** Basal metabolic rate, 225

FRASER: Standard of cure in syphilis, 563.
Reaction of the blood in dyspnoea, 609
FREE: Liminal in epilepsy, 177
FREE: The coexistence of syphilis and tuberculosis in lymph glands, 437
FREUDENBERG: Treatment of infantile tetanus with ammonium chloride, 357
FREY-BOLL: Caesarean section under local aesthesia, 394
FRUMKIN: Progressive muscular dystrophy, 2
Fruits, dried, antiscorbutic value of, 323
FUCHS: The kidney affections of pregnancy, 221
FUCHS: Distribution of the nitrogen in the protein of chicken sarcoma, 349
Fusiform bacillus bacteraemia, 496

G.

F

Galactoecele, 489
GALAGUTIC: Treatment of the appendix stump, 485
Gall bladder, cholelithiasis and carcinoma of, 262
Gall bladder lesions, 260
Gall stones, early for mation of in typhoid fever, 387
GAND: Hypertrophic rhinitis in the child, 551
GANDHYPAG: Experiments with antivenereal prophylaxis, 17
Gangrene, diphtheritic, of the vagina, 69
Gangrene of the lung, 108
Gangrene, post-pneumonic, 163
Gangrene, pulmonary, treatment of, 79, 108
Gangrene of a uterine myoma after the menopause, 19
GARDEN: Lethargic encephalitis and pregnancy, 89
Gas-containing abscesses of the liver, 359
Gas oedema complicating typhoid fever, 429
GASTRIC: The unity of herpes, 247
Gastric ulcer. See Ulcer
GAX: Clinical reactions in the treatment of dermatoses by auto-haemotherapy, 99
GELLHORN: Present theories in gynaecological treatment, 392
Germany, frequency of abortion in, 121
Gestation, ectopic, 368
Gestation, fetal, espiogotomy for, 468
Gestation, coexisting uterine and ectopic, 42
Gestation. See also Pregnancy
GETTINGS: Administration of fluid in infantile diarrhoea, 306
GIBSON: Non-operative treatment of empyema, 575
GIESECKE: End-results of treatment of cancer of the uterus and vagina, 606
GIRFORD: Peripheral iridotomy in glaucoma, 33
GIRARDI: Sequelae of encephalitis lethargica, 404
GIVEN: Results of dental defects, 546
Gland, cervical, neoplasms of, 291
Gland, thyroid, operations on, 238—And immunity, 614. See also Thyroid
Glands, lymph, the coexistence of syphilis and tuberculosis in, 457
Glaucoma, peripheral iridotomy in, 337
Glaucoma, trephine operations for, 573
Glomerular haemaneurysm. See Haemaneurysm
Glycose, intravenous injections of in pruriginous skin diseases, 273
Glycosuria and diabetes in pregnancy, differential diagnosis of, 167
Glycosuria, renal, 588—As an early sign of pregnancy, 220
GORDIAN: Nonne's four reactions in syphilis, 722
GÖTTFE, exorbthalmic: X-ray treatment in, 477—And digitalis, 501—Basic metabolism in, 538
See also Graves's disease
Gold salts in the treatment of tuberculosis, 483
Gold-sol test in mental disease, 275
GONNELL: Dequamation of the bladder epithelium in uremia, 87
GONOCOCCAL arthritis treated by intramuscular injections of sporicidal fluid, 87
GONOCOCCI in the preputial folds, 665
GONORRHOEA treated by cedar-wood oil, 34
GONORRHOEA, results of treatment for, 86

E.

[illegible]

Gonorrhoeal infection of epididymis and tunica vaginalis, 85
GORDON: Progressive cerebral hemiplegia, 549
GOSIO: Pfeiffer's bacillus and influenza, 449
GOUGEROT: Syphilis without a chancre, 128
GOTTLAND: Myomectomy, 563
GRAEBER: Rapidity of development of uterine myomata, 43
GRAN: Strauss's water test in orthostatic albuminuria, 154
Grape-sugar injections in dermatology, 103
Grape-sugar injections and salvarsan, 102
Graves's disease, influence of underfeeding on, 479. See also Goitre
GREEN: Calcium lactophosphate in cyclic vomiting, 383
GREEN: Chronic diffuse nephritis in childhood, 566
GREENHAUM: Yeast infections of the skin, 325
GREENHAL: Unusual exanthem resembling measles in infants, 406
GRIG: Naevus of the meninges, 437
GRIFITH: Value of butter-flour in infancy, 33
GRON: Bird-mite dermatitis, 130
GROSS: Cervical carcinoma and pregnancy, 559
GROSS: Galactocoele, 489
GROSS: Erythema nodosum, 55
GROENOT: The bismuth treatment of syphilis, 51
GUILLAIN: Lethargic encephalitis and pregnancy, 89
GULEKE: Echinococcosis and actinomycosis of the spine, 164
GUNSETT: Treatment of sciatica, 334
GURN: Ambulatory treatment of chronic ulcers of the leg, 288
GUTHRIE: Experimental inoculation of human throats with virulent diphtheria bacilli, 122
Gynaecological diagnosis, x-ray examination of the pelvic colon in, 365
Gynaecological practice, heliotherapy in, 344
Gynaecological treatment, present tendencies in, 392, 393
HYUNG: Treatment of infantile tetany with ammonium chlorido, 357

H.

Haemangiectases, glomerular, in the nephritis of typhoid fever, 70
Haematuria, a phenolphthalein test for, 246
Haematuria from rupture of a vesical varix, 508
Haemolytic streptococcal and obstetric prognosis, 340
Haemophilic bacilli, 612
Haemoptysis and pulmonary tuberculosis, 380
Haemoptysis due to tuberculosis, treatment of, 106
Haemorrhage, "idiopathic," the course of, 242
Haemorrhage, intracranial, of the newborn, lumbar puncture in, 192
Haemorrhage during and after tonsillectomy, 185
Haemorrhage from the non-pregnant uterus, pathology of, 142
Haemosiderosis of pernicious anaemia, significance of, 520
Haemostasis in suprapubic prostatectomy, 160
Haemostatics, various, the efficiency of, 362
Hair, brittleness of, 2
HALLAN: Peritoneal tears produced by myomata, 92
HALLOPEAU: Vaccines in osteomyelitis, 58
HALPHEN: Treatment of whooping-cough, 151
HANSEN: Surface tension and the action of antibiotics, 149, 298
HANSEN: A statistical survey of the treatment of fractures, 557
HARRIS: The prostatic syndrome without evident enlargement, 11
HARTSHORN: Fracture and dislocation of cervical vertebrae without paralysis, 475
HARVEY: Bacterial virulence in relation to vaccine production, 587
HARVIER: An experimental study of lethargic encephalitis, 248—Encephalitis lethargica, 519
HASSENCAIR: Novasitrol as a diuretic, 254
HAUDEK: X-ray treatment in exophthalmic goitre, 407
HAVERATE: Late recovery from katatonie, 129
Headache, relation of to functional monocularity, 414
Heart disease, relation of embolism of the limbs to, 303
Heart disease in pregnancy, 292
Heart disease, prognosis in, 255
Heart disease, the pulse deficit in the control of, 28
Heart failure acute, intracardiac injections of adrenaline in, 137
Heart, streptococcal infections of, 296
Heat-stroke, experimental immunity to, 95
Hegar's sign of pregnancy, 243
HEBERG: Lupus treated with general carbon arc light baths, 409
Heliotherapy in gynaecological practice, 344
HELLER: Local use of acetyl-salicylic acid, 263—The effect of mercury in syphilis, 451
HELLMUTH: Bilirubinaemia in the newborn, 126
Hemiplegia, progressive cerebral, 549
HENNEBERG: Fatal cerebral lesions after salvarsan treatment, 354
HENROTAY: Syphilis as a cause of foetal malformations, 539

HERBURN: Trophic operations for glaucoma, 578
HERBERT: After-treatment of small-flap sclerotomy, 532
Hernia, abdominal, 309
Hernia of the bladder, etiology of, 580
Hernia, diaphragmatic, 533
Hernia, femoral, radical cure of, 308
Hernia, sliding, 411
Hernia of genitals, virulence of the cerebro-spinal fluid in, 124
Hernia, intercostal, following tuberculous pleurisy, 356
Hernia, umbilical, 247
HERMANN: X-ray treatment of tonsillar and adenoid tissue, 282
HERNANDEZ: The nervous child, 596
HERWAT: Acute otitis media and mastoiditis treated by Schwartz operation, 115
Hiccup, epidemic, 158
Hiccup, treatment of, 302
HIRSH: Treatment and prophylaxis of puerperal fever, 267
HIGLEY: Relationship of blood groups to disease, 273
HILLENAND: Displacements of the trachea, 178—Variations in the antibody content of the serum in phthisical patients, 610
Hilum tuberculosis. See Tuberculosis
Hip, congenital dislocation of, 602
HUSCHNABAUER: Treatment and prophylaxis of puerperal fever, 267
HUTCHINSON: Blastic and respiratory displacement of the normal kidney, 30
HUTCHINSON: Treatment of sciatica, 165
HÜLLER: Treatment of sciatica, 161
HOLDEN: Operative treatment of chronic adnexal disease, 93
HOLST: Rheumatic myocarditis, 48
HOLST: Diagnostic value of the excreta temperature in tuberculosis, 547
HOLZAPFEL: A rare cause of atresia of the vagina, 470
HUGHESON: Treatment of arterial hypertension, 505
HOWE: Staphylococcal haemolysis, 521
HÜLSE: Vaso-constrictor substances in the blood in high blood pressure, 374
Humerus, erect dislocation of the, 465
HUNZIKER: Small-pox and flies, 595
HUND: Acute infections of the nasal vestibule, 415
Hutinel's disease, 14
Hydatid cyst of the kidney, 363
Hydatid disease, antimony treatment of, 545
Hydatid disease of the spleen, 511
Hydatid disease, failure of tartar emetic in, 377
Hydatid fibril, 109
Hydatidiform mole and chorion epithelioma, 604
Hydrocele of the kidney, 37
Hyperemesis gravidarum, 398—Treatment of, 518
Hypertonus and diabetes, 127
Hypodermatitis, 454
Hypopituitarism, epileptoid attacks in, 307
Hysterectomy, abdominal, before removal of the cancerous rectum, 68
Hysterectomy, pro-Caesarean, 514
Hysterectomy, supravaginal, combined with interposition for procidentia, 67

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

LONDON: SATURDAY, JANUARY 7TH, 1922.

An Address
ON

CERTAIN ASPECTS OF PAIN.

DELIVERED BEFORE THE SHEFFIELD MEDICO-CHIRURGICAL
SOCIETY, DECEMBER 8TH, 1921.

BY
HENRY HEAD, M.D., F.R.S.

PAIN and discomfort are the oldest defensive reactions of the organism, and potentially unpleasant stimuli form the basis of most primitive reflexes. Even the simplest animal shows pain and moves in the direction of pleasure. All such impulsive actions allow of little choice, and any part of the body exposed to a harmful form of stimulation is urgently withdrawn. Sensory impulses capable of evoking pain or discomfort are therefore most important factors in the life of even the highest organism, although their action may be almost automatic.

In man, however, where they not only cause impulsive reflexes, but also produce conscious discomfort, pain is the most urgent symptom with which the medical man is compelled to deal. At the same time it forms one of the most important diagnostic aids, if rightly interpreted. But in so many cases its meaning is misunderstood; the intensity of the patient's suffering cries for relief, and attention is more often focussed on easing the pain than upon its diagnostic significance. These difficulties of interpretation are greatly enhanced by misunderstanding of what is generally comprised under the term "pain." Almost any stimulus of great intensity is liable to produce discomfort. Ticking the sole of the foot is extremely disagreeable, but in no circumstances can it be strictly said to be painful. Localized pressure, steadily increasing in amount, becomes more and more uncomfortable, until at last it evokes a sensation that can be justly called pain. But when a faradic current is applied to a sensitive part like the foot, the first disagreeable sensation is strictly one of pain, and the impulses upon which it is based pass up the spinal cord in adjacent and analogous tracts to those for heat and cold. Supposing, however, that these paths are interrupted, so that the patient cannot experience pain in the strict sense of the word, a strong faradic current, which appears to him first of all as a kind of tingling, will rapidly become so disagreeable that he will draw the limb exactly as if he was still exposed to painful impressions. At the same time he may complain that it causes intense discomfort.

Obviously, then, what is popularly called pain may contain two elements: First of all, there is a true specific sensation, exactly equivalent to that of heat, cold, and touch. Secondly, there is discomfort or that unpleasant feeling tone, which

may accompany many other sensations besides those which have a right to be called specifically painful. This unpleasant feeling may be associated with touch in the form of tickling or itching, with pressure, as an intolerable sensation we call "crushing pain," with heat as "burning," and with cold as that disagreeable state that we know so well when our hands and feet are chilled.

But it is a matter of no importance from the point of view of the organism whether the sensation evoked be a strictly specific one of pain, or what should be more truly called discomfort. Both lead to the production of reflexes that tend to remove the affected part, or even the whole animal from the place or object productive of such unpleasant experiences. Reactions of this kind are impulsive and urgent; once they come into being, the movements they produce are uncontrolled; they permit of no choice. It is therefore most important that the impulses which underlie any of these disagreeable sensations should be diminished in extent, or actually inhibited, in favour of those sensory impressions more capable of leading to discriminative action. But, on the other hand, the mechanism underlying the production of pain and discomfort must remain in full

physiological activity, so that it can play its part in defence of the organism, whenever noxious stimuli reach a high grade of intensity.

Such dominance of a higher centre over the activities of another, subserving more primitive modes of response, is exemplified by the relation between the cortex and optic thalamus. This is the end-station for all those afferent impulses subserving the more affective forms of sensation, such as pain, heat, cold, tickling and all forms of discomfort. On the other hand, the functions of the cerebral cortex are responsible for the more discriminative aspects: the appreciation of size, shape, weight, texture, together with the relative intensity and spacial relationships of various external stimuli. These two sensory centres are not independent of one another, but the activity of the cortex exerts a dominant influence over the response of the optic thalamus. Now it sometimes happens that a gross organic lesion destroys the path of these controlling influences, and the thalamus is set free to manifest its reactions unchecked. Every stimulus capable of evoking discomfort or pain, and even in some cases pleasure, now produces an exaggerated effect on that half of the body opposite to the lesion.

Here we see expressed, in the form of two anatomically separable centres, that dominance of higher and more discriminative functions, over those inducing impulsive reactions, which is so characteristic of the activity of the central nervous, laws are at work in painful manual origin; but here no structural controlling mechanism from the these potentially disagreeable impulses,

FIG. 1.—To represent diagrammatically the anatomical arrangement of the paths and centres concerned in sensation. Two distinct paths exist in the spinal cord: a crossed secondary path in the ventrolateral column, which conveys impressions of pain, temperature, and tactile impulses to the opposite hemisphere in the dorsal column, which also conducts tactile impulses, together with those that underlie the sense of posture, appreciation of movement, discrimination of two points, and the recognition of vibration, size, shape, form, weight, etc. The second path is represented in the medulla oblongata, but separates from the first path, at least as high as the pons. All these secondary sensory fibres, now crossed, terminate in the ventro-lateral region of the optic thalamus. Here the impressions they carry are registered in the cerebral cortex. The second path, the one carries impulses to the cerebral cortex, the other towards the more mesial parts of the optic thalamus. In addition, fibres pass from the cortex to terminate in the lateral nucleus of the optic thalamus. From Head and Brown, *Principles of Psychology*, vol. xxiv, p. 172, and *Studies in Neurology*, vol. II, p. 533.

We are now dealing with a delicate equipoise, which can be upset by additional weights thrown into either scale.

Pain of Visceral Origin.

Afferent impulses from the viscera do not normally enter consciousness. The eupeptic knows nothing of the processes of digestion beyond a gentle sense of well-being; but under normal conditions afferent impressions from the internal organs are capable of arousing pain and discomfort. Some have tried to maintain that the viscera are "insensitive" and incapable of generating afferent impulses of this order; but no one who has ever suffered from the passage of a renal calculus or a true referred pain from inflammation of the pulp of a tooth will look upon such statements as anything but hair splitting dialectic. All power of conscious response to heat, cold, and touch is certainly absent from the great part of the stomach and intestines, and pain cannot be produced by burning, cutting, the prick of a pin or other sharp instrument. Internal surfaces are unable to respond to such artificial stimuli to which they have never been exposed during the life of the individual or the race. But the hollow viscera, such as the stomach and the bladder, react briskly to changes in tension, which are their natural mode of stimulation.

Even if a stimulus is capable of exciting these sheltered parts of defective sensibility, it does not usually produce a sensation on account of the resistance of the nervous system to such potentially disagreeable impressions. But a sensory response may follow, whenever these visceral impulses become sufficiently strong to overcome the inhibition by which they are normally held in check, or when the forces opposing their passage are in any way diminished. Once the path has been opened and the dominance of the higher centres overcome, a weaker visceral stimulus will be followed by sensation; to this diminished resistance is due the production of pain from otherwise inadequate causes, especially where visceral irritation has been long continued.

Bearing these facts in mind, let us examine some actual examples of pain produced by visceral disease and see to what further laws we are led by such consideration.

Now, we have reason to believe that the viscera have a double afferent supply. One of these corresponds to that

becomes agonizing during the long deep inspiration which follows a cough, a laugh, or a sneeze. It is absent when the side is at rest, and is relieved by any treatment that fixes the chest, such as successful strapping.

This pain is frequently associated with tenderness on pressure or percussion in the intercostal spaces. By this means an area of distinct deep tenderness can sometimes be marked out, and it is within these limits that pleuritic friction can usually be heard. The pain and tenderness seem to be due definitely to inflammation of the parietal pleura and possibly even to that which covers the lung; both disappear when serous fluid is effused, but may persist over the upper border of purulent effusion in empyema.

Whenever a serous cavity is affected and the parietal wall is inflamed, local tenderness of this kind, evoked by deep pressure, is liable to make its appearance. This is often of profound diagnostic value. With pericarditis it is frequently possible to elicit tenderness on pressure. Placing the end of the stethoscope lightly upon the chest in an intercostal space produces no pain, and friction may not be audible, but, on increasing the pressure, not only does the patient complain of pain, but the rub becomes more evident. Such an association between the increase of tenderness on pressure and the clearness with which friction becomes audible is often an equally definite diagnostic point in pleurisy.

In many cases of inflammation of the appendix the same law can be applied. In the early stages, before perforation has taken place, widespread pains may be present in the abdomen, corresponding to the afferent supply of the upper parts of the digestive tract. Such pains are due to

abnormal movements of the stomach and intestine, and express the reaction of normal parts to a lesion situated in some allied physiological system. But when the appendix becomes perforated and inflammation of the peritoneum ensues, these referred pains are replaced by local manifestations, accompanied by deep tenderness over inflamed parts. Sometimes it is difficult to determine whether tenderness of the abdominal wall is due to its deeper or more superficial structures, and whether it has a local significance or is part of the manifestations of a referred pain. This can be decided by the following method of examination: When the pain is due

FIG. 2.—To show the area of deep tenderness evoked by pressure or percussion in a case of acute pleurisy. (From *Brain*, 1896, vol. xix, p. 233.)

FIG. 3.—To show the superficial tenderness present in a case of aneurysm of the ascending portion of the aorta. (From *Brain*, 1896, vol. xix, p. 171.)

deep system, which in the limbs supplies muscles, tendons, and joints; this remains intact when all cutaneous nerves are severed. The peculiar aptitude, possessed by a part innervated from this deep afferent mechanism, is the power of responding to stimuli, which produce alterations in form or pressure. Excessive tension may even evoke pain, and "cramp" is the reply of the end-organs of this system to abnormal muscular contractions. Parts innervated in this manner are insensitive to light contacts, pricking, heat and cold; but they are endowed with definite local signature, and the patient is capable of appreciating within certain limits the site of the stimulated spot.

Thus, when the pleura is inflamed, the pain, stabbing in character, is intensified by every respiratory movement, and

FIG. 4.—To show the distribution of the eruption in a case of herpes zoster. Examination showed an inflammatory lesion posterior root ganglion. (From *Head and Neck*, vol. xxiii, p. 439.)

to local peritonitis, the loin is not tender either to superficial stimulation or to deep pressure; but on passing steadily forwards a point is at last reached, about the level of the tip of the eleventh rib, where pressure evokes pain. In front of this a considerable area of deep tenderness can usually be discovered occupying the right iliac fossa. Had the pain been referred, superficial tenderness would have been found in the loin corresponding to the posterior portion of the segmental areas affected.

When serous membranes, such as the pleura, pericardium, and peritoneum, are inflamed, the pain has a definite local significance, and the tenderness is increased by pressure—in fact, these cavities behave like the inner surface of joints.

This deep system of afferent nerves supplies not only the muscular and other subcutaneous tissues of the limbs and trunk, but also innervates similar parts of the internal organs. Some forms of colic belong to this order; they are the equivalent in the intestine of muscular cramp. Abnormal movements produce disagreeable sensations, associated with distinct impressions of some change in posture. These are the conscious results evoked by the painful aspect of those proprioceptive impulses, which Sherrington has shown to have

FIG. 5.—To show the superficial tenderness present in a case of aneurysm of the aorta. (From *Brain*, 1896, vol. xix, p. 175.)

so profound an influence on the regulation of posture and movement.

But the majority of pains arising from visceral disease have not this localizing value. They are referred into parts remote from the site of the lesion. They cannot be interpreted without a knowledge of the relation of afferent impulses to the segments of the central nervous system.

The distribution of the pain in a man who suffered from an aneurysm of the first part of the aorta is illustrated in Fig. 5. The point of greatest intensity was situated just above the inner condyle of the humerus; distinct superficial tenderness was present over the area marked on the figure. To what does this area correspond?

You are aware that the common form of herpes zoster is due to inflammation of the posterior root ganglion. Now it so happens that, when this structure is subjected to a violent irritative process of this kind, severe necrotic changes occur over the peripheral distribution of certain of its fibres associated with severe pain in its centripetal manifestation. The system to which these fibres belong is what Bayliss called "autonomic"; they are capable of conducting impulses in either direction according to the specific nature of the end-organs to which they are attached. Some of them conduct

centralwards like all other afferents, and their impulses evoke pain and discomfort; others produce a so-called "trophic" effect on the periphery.

Thus, by a fortunate chance, the extent of a herpetic eruption, when fully developed, represents the distribution of the fibres of this system which pass through some particular ganglion. Now, the distribution of these fibres corresponds closely with the segmental arrangement of painful impulses in the spinal cord; consequently, it is possible, by studying the extent of the eruption in cases of herpes zoster, to obtain a knowledge of the form assumed by the areas of segmental

FIG. 6.—To show the extent of the superficial tenderness in a case of mitral stenosis. The mitral valve was a long buttonhole slit, extremely rigid, with fine beaded vegetations on the free surface of the valve. The left auricle was dilated; its wall was tough and fibrous. The muscular substance was diminished, except round the base of the appendix where it was hypertrophied. (From *Brain*, 1896, vol. xix, p. 192.)

distribution and also their numerical significance.

I therefore give a drawing of a case of herpes zoster, which was proved by post-mortem examination to be due to inflammation of the second thoracic posterior root ganglion. (Fig. 4.) You will notice how extraordinarily closely its distribution corresponds with that of the tenderness present in the man who suffered from aneurysm.

But such isolated and restricted areas of pain and tenderness rarely occur as a consequence of visceral disease; they are of great scientific interest but of little practical importance. The next figure (Fig. 5) shows a more common condition produced by aortic disease. The tenderness not only occupies the second thoracic area, but spreads into parts supplied by the nerves of the cervical plexus.

The next figure (Fig. 6) shows the extent of the tenderness in a patient who suffered from severe mitral stenosis, where the rigid slit-like valve permitted some regurgitation. I give for comparison, first (Fig. 7) the distribution of a herpetic eruption, proved by post-mortem examination to be due to inflammation of the sixth thoracic posterior root ganglion, and then another (Fig. 8) showing the parts supplied by the seventh thoracic. It is obvious how closely the pain and tenderness in the case of mitral stenosis corresponded to the sixth and seventh thoracic areas.

To what, then, are these areas of referred pain and tenderness due? It is evident

that they must be produced by abnormal physical conditions within the cavities of the heart or the aorta. Tension is the most effective stimulus to any hollow organ; experiments on the gall bladder have shown that it may be cut or burnt without the production of any reflex changes, but the injection of even a small quantity of fluid so as materially to raise the pressure, will cause a profound disturbance due to the afferent impulses so generated. But to return to the conditions within the heart: it is obvious that in such a case of mitral stenosis as I have just mentioned, the work of the auricle is obstructed by the severe narrowing of the orifice, and in addition, blood is forced back into it, at the moment of its diastole, from the contracting ventricle through the incompetent valve. These abnormal conditions set up afferent impulses which pass to the central nervous system. There they excite certain segments of the spinal cord to such an extent, that all potentially painful impulses passing into them produce an exaggerated effect. Certain areas on the body, such as those shown in Fig. 8, become tender to such stimuli as the dragged point of a pin, or pinching up the skin between the thumb and forefinger.

The balance of afferent impressions in the central nervous system is upset by the potentially disagreeable impulses impinging on these segments of the spinal cord. At first the central resistance may be sufficient to inhibit them, or at any rate to prevent a disturbance of consciousness. But, if they

FIG. 7.—To show the distribution of the eruption in a case of herpes zoster. This proved on post-mortem examination to be due to inflammation of the sixth thoracic posterior root ganglion. (Read and Campbell, *Brain*, 1920, vol. xxiii, p. 470.)

FIG. 8.—To show the distribution of the eruption in a case of herpes zoster. This proved on post-mortem examination to be due to inflammation of the seventh thoracic posterior root ganglion. (Read and Campbell, *Brain*, 1920, vol. xxiii, p. 471.)

are sufficiently intense or of long standing, sensation is aroused; the pain is then projected to those parts of the surface of the body supplied by the affected segments, and these areas become tender, reacting excessively to any potentially disagreeable stimulus. They therefore reveal the afferent supply of the organ, which gave rise to the potentially painful impulses. It is obvious, therefore, that certain abnormal conditions of tension within the auricle can produce pain and tenderness, referred to the sixth and seventh thoracic and adjacent segmental areas. On the other hand, diseased conditions of the aorta and the ventricle may be associated with similar areas higher up on the chest, or in the region of the third and fourth cervical.

For the explanation of this remarkable phenomenon it is necessary to recall the embryological development of the heart. Evidently its afferent visceral innervation is upside down in relation to the present position of the adult organ. At one stage of its development, the heart consisted of a single tubular vessel, the hinder end of which was continuous with the great veins, whilst the anterior end bifurcated into two primitive aortae. At this time the heart lay in the middle line and clearly showed a division into three chambers; the hindmost of those becomes the auricle, the middle portion the ventricle, the most headward the bulbus aortae and ultimately the ascending arch of the aorta. This tube then becomes bent on itself, so that the hindmost or auricular portion comes in the adult to lie higher than the middle or ventricular portion.

Thus, the plan upon which the sensory supply of the visceral afferent system is laid down seems to be very antique and to represent an early stage of vertebrate development. Afferent impulses from the heart enter the segments of the central nervous system, just as if the auricles were still the hindmost portion of the heart and as if it was a median organ. Moreover, the segments affected jump from the fourth cervical to the first or second thoracic, omitting the upper limb, which has budded out at a later stage of development.

It will be noticed that Figs. 5 and 6 show not only areas of tenderness upon the trunk, but also upon the scalp. This is an aspect of referred pain arising from visceral disease which has been unaccountably neglected. It is obvious that, if some organ in the head, such as an eye, ear, or tooth, is affected, referred pain may be produced occupying areas on the face or scalp. But it is not usually recognized that tenderness, due to afferent impulses from some organ in the thorax or abdomen, may be accompanied by areas of tenderness on the scalp. What is the explanation of this remarkable phenomenon?

I must again ask you to follow me in certain developmental considerations (Fig. 9). That nucleus of the trigeminal nerve which supplies the greater part of the scalp, together with central connexions of the first and second cervical, form the somatic portion of a great complex of segments of which the visceral part is represented by what may be called the vago-glossopharyngeal. This supplies afferent fibres to the heart, the lungs, the oesophagus, stomach, and upper part of the intestine.

Now we have already seen that, when visceral afferent end organs are exposed to a suitable stimulus capable of exciting them to action, impulses are poured into the central nervous system, and parts on the surface of the body in connexion with those segments become tender and over-react to external stimulation. Supposing that some organ supplied with afferent fibres from what may be called the vagus-complex sets up such impulses, the scalp becomes tender, because it is that portion of the surface of the body which is in direct relation with the excited segments.

The site of the headache and tenderness does not indicate directly the organ which is responsible for their production; they cannot be classed as "cardiac" or "gastric" neuralgias. The position of the tender areas on the scalp depends more on the segmental level of innervation of the painful focus than on the actual organ affected. Thus, the higher the areas of tenderness present upon the trunk, the further forward will they be found upon the scalp and vice versa.

Spread of Visceral Pain and Decreased Central Resistance.

Referred pain of visceral origin and the tenderness which accompanies it may be confined to the territory of a few

segments only, representing the nerve supply of the affected organ. But in the larger number of cases met with in daily practice this is not the case; if the stimulus is extremely severe—as, for example, during an attack of gall stones or renal colic—the pain may spread widely, even in otherwise normal persons; not only does it become bilateral, but it is liable to extend both upwards and downwards into regions that stand in no direct nervous relation with the affected organ (Fig. 10).

Should a referred pain become chronic, this forms an even more important cause for its diffusion; it tends to spread by the fact of its duration. For not only is the general resistance of the patient worn down by the disease, but the passage of painful impulses is facilitated by time; impulses can now excite pain which previously failed to do so.

Certain segmental areas seem to make their appearance with especial ease when central control is diminished, although they are situated far apart upon the body; thus, pain in the loins or over the forehead is liable to occur whenever general resistance is lowered. Organs, such as the uterus and breast, stand in close mutual connexion, and within twelve hours of labour referred pains not uncommonly appear in the front of the chest and in the scapular regions. These come and go with the "after-pains," and can be increased by the action of ergot or by manipulating the uterus.

These phenomena of generalization or spread of visceral pain and tenderness are of such common occurrence that they form an important factor in the clinical picture of many diseases. Diffusion of potentially painful impulses is normally prevented by that natural inhibition exercised by the central nervous system over disagreeable impressions; once this is relaxed, they spread widely. Normally, they would have been prevented from influencing consciousness, or would have been strictly confined to areas appropriate to the organ affected.

Certain general bodily states form potent causes of such diminished automatic control. Of these, menstruation is one of the most important in women. This physiological act may be accompanied by referred pain, confined strictly to those segments which stand in direct relation with the pelvic organs; or the morbid sensations may occupy the whole of the body and lower extremities below the level of the umbilicus, with or without the cervical areas and occipital region of the scalp; finally, the head, trunk, and even the limbs may become painful and tender in parts that have no direct relation to stimuli within the pelvic organs. The extent to which such widespread generalization occurs depends more on the temperamental condition of the patient than on the intensity of the painful irritation or severity of the underlying organic changes.

Many women have a tendency to be what is called "neurasthenic"; strictly speaking, this unsatisfactory term should be confined to symptoms expressive of chronic nervous exhaustion. This state is characterized by a profound diminution of general control, exercised in the nervous system by the activities of one level over those of a lower one. This applies not only to physiological processes in the spinal cord and lower parts of the brain, but also to the mental

activities of the patient. Attention wanders, memory is defective; sleep, that most salutary means of increasing central control, fails. Under such circumstances any cause for pain, even the normal passage of blood through the lower segments of the uterus, may start painful impulses, which, in consequence of diminished automatic resistance, spread widely over the body.

A sudden rise of temperature frequently causes widespread generalization of pain: Follicular tonsillitis or any parenchy-

FIG. 9.—A diagram to explain the occurrence of headache and superficial tenderness of the scalp due to some affection of an organ within the chest or abdomen.

FIG. 10.—The upper figure shows the superficial tenderness which was present before an attack of paroxysmal pain of cardiac origin. The lower figure shows the wide diffusion which appeared when the attack was over. (From *Brain*, 1895, vol. xix, pp. 210-211.)

matons affection of the tonsils is frequently associated with superficial tenderness on the same side, extending from the lower part of the mastoid almost to the middle line in front; this I have called the "lyoid" area. Suppose, however, that the onset is sudden and is associated with fever, we may now discover pain and tenderness on both sides of the neck, over the forehead, the occipital region, and even in the back or other parts of the body or limbs.

Anaemia is another cause of diminished general resistance to painful impressions. The patient may be profoundly anaemic and yet suffer from no pain or tenderness; but as soon as some source of pain is present, it at once begins to spread; toothache in an anaemic patient is a diffuse affection, extending far beyond the areas directly connected with the affected organ. If the local cause is removed, pain does not of necessity cease, at any rate immediately; for when central resistance has once broken down, control is recovered with difficulty.

In all these cases the pain originated in some definite and recognizable cause; it spreads widely because of the severity or long duration of the stimulus, or in consequence of the relaxation of central control. But sometimes pain and tenderness of this order may become widely diffused, in consequence of some debilitating psychological state, such as anxiety or emotional shock. Neuralgia and superficial tenderness of dental origin not uncommonly assume undue proportions owing to insomnia and worry, and the mental state of the patient has a notoriously profound influence over pains originating in the pelvic viscera.

Occasionally, central resistance to potentially disagreeable impulses is temperamentally so low that pain may appear without any obvious cause for peripheral stimulation. Some women are rarely free from tender spots in various parts of the body, representing the maxima of one or more of these tender areas. They form foci from which pain may generalize widely under the influence of emotion or other conditions, which lessen the dominant power of higher centres. No gross visceral stimulus is required. The central apparatus is already in an explosive condition, and any relaxation of physiological control leads to an outburst of energy manifested in widespread discomfort. In such cases, the order in which the phenomena appear does not follow rules that can be laid down for pain of visceral origin. Severe pain over the lower part of the abdomen and back may be accompanied by headache and tenderness situated over the forehead; the trunk can be widely affected without the head and neck, or vice versa. Such want of harmonious correlation points to the central origin of these morbid phenomena; they are not the direct expression, however extensive, of peripheral stimulation.

If we responded constantly and inevitably to all stimulation of peripheral end-organs, we should be automata, the victims of indiscriminate reactions. But, with the gradual evolution of its functions, the central nervous system acquires ever-increasing control over afferent impressions produced by the action of external forces. Such development takes place not only in the race, but in the life of the individual; and it is to this that we owe our power of acquiring new reactions and facilities.

Even in the fully developed nervous system of man, the acquisition of some new aptitude is associated with increasing central control over sensory impressions; we learn to adapt ourselves to the conditions around us, and cease to be the victims of unco-ordinated reactions. These are controlled or suppressed, not by the will, but by the power of adaptation, which is one of the most potent automatic factors in the activity of the central nervous system.

During the evolution of function, the power of responding in a more primitive manner is not lost. The mechanism of the older and more immediate reaction remains intact; but its activity is held in check, ready to become manifest, should the noxious stimulus grow unduly intense. Everyone, however healthy, is liable to suffer from pain during the passage of a renal calculus. But, in states of disease, this automatic control is likely to break down, less from the violence of the stimulus than from causes which lower physiological vitality. These may be both physical and mental; exhaustion and anaemia are no more potent than fear and anxiety.

The extent of this automatic control over sensory impressions not only varies from time to time, but is subject to extreme temperamental differences. As an automatic process, it takes its place with the other subconscious activities,

Pain and discomfort are among the most important of these conditions. I hope I have convinced you that, when the afferent impulses underlying these sensations and affective states impinge on the central nervous system, they disturb its balanced activity as a whole. The result they produce depends on the constitution of the organism, and not only on the site of the affected organ or the nature of the disease.

An Address

ON

PROBLEMS INVOLVED IN THE CONGRESS OF THE SEXES IN MAN.

DELIVERED TO THE OXFORD MEDICAL SOCIETY

BY

ARTHUR THOMSON.

LESLIE PROFESSOR OF ANATOMY, OXFORD.

I AM deeply sensible of the honour you have conferred upon me by inviting me to give your annual address. I confess in many instances such appeals are rather irksome—for they entail the preparation of an elaborate address. Now the delivery of such addresses is not in my line, and to impose on you the dreary task of listening to one would, I feel certain, not be fruitful of any good results. But in this instance I welcome the invitation, since it provides me with an opportunity of acquiring much-needed information, based on personal experience. Doubtless in the practice of your profession many of you must have pondered over some of the problems it will be my privilege to submit to you, and it will be to everyone's advantage if you will freely express your opinion.

My address, if address it can be called, will rather take the shape of a statement of the problems which still beset us in our attempt to unravel the mysteries of Nature.

Who that has studied the structure of the mucous membrane of the uterus has failed to be struck by the richness of its glandular elements? When we proceed further, however, and come to inquire what the function of these glands may be, we are at once plunged into the realms of uncertainty. The generally accepted views are far from satisfying. We are told that it is an admirable arrangement whereby Nature provides a suitable bed in which the impregnated ovum may be nourished, but a little reflection proves that this is not altogether a satisfactory explanation. The fertilized ovum, through the agency of its outer or trophoblastic layer, possesses the remarkable power of making a bed for itself, as exemplified in the many instances on record of extra-uterine foetations. May I recall to your memory the fact that the zygote may establish perfectly effective nutritive relations with the tissues with which it may happen to be in contact, be they tubal, peritoneal, or ovarian? The effective cause of its final destruction is the absence of such mechanism as the uterus provides for its ultimate expulsion into the outer world. This, and the fact that, according to modern views the glands play no part in the formation of the placenta, disproves the theory that these glands are an essential feature in the mechanism necessary to establish a nutritional connexion between the mother and the foetus.

As glands, what then is their function? Are they secretory or absorbent? In truth the views on the subject are very vague. Marshall,¹ a recognized authority on the physiology of reproduction, is discreetly silent on this subject, though he quotes the opinion of others to the effect that in the premenstrual period the increase in the size of the glands is supposed to be due to a collection of the secretion of the gland cells within the lumen of the gland.

Young,² in discussing the changes in the mucosa prior to and during menstruation, referring to the factors concerned, says: "Whether these are due to an activity of a secretory nature on the part of the epithelial cells, or whether an activity on the part of the stroma, also secretory in nature, can only be a matter of theory." On the other hand, whilst describing the pre-embedding changes in pregnancy, he describes the changes which occur in the pig as of the nature of marked "infiltration of the superficial layers of the mucosa with lymph. At the same time there is an active glandular secretion in process which leads to a marked ex-

are free for a considerable time, and where apparently there is need for some such nutritive material as has been referred to as "uterine milk." He admits that, whilst it seems unlikely that the minute human ovum can exert, before attachment, anything more than a small influence on the uterine mucosa, yet, where it comes to rest, the structure of the mucosa would be so altered as to permit of a ready flushing of the subepithelial tissues with fluid and blood in response to the extra-chorionic activity. As will be observed, this conclusion is of a purely speculative kind, and there is no material evidence in support of it.

So, too, is the opinion expressed by Fujimura,⁴ in a recent paper, that a part of the secretion and detritus of the uterine glands, at least in a little advanced stage of pregnancy, are naturally absorbed by the mother on account of the closure of the ducts.

I have quoted from these authorities because most of the physiological textbooks I have consulted are silent on the matter. There is one investigator, K. Boiling,⁵ who expresses his opinion in no uncertain words. In a research entailing the examination of many animals (mole, rat, rabbit, guinea-pig, dog, cat, pig, calf, cow, sheep, goat, deer, horse, orang, but not including man), he comes to the conclusion, based on his own personal observations, that mucus is only present on the surface epithelium of the cervical canal, and that the uterine glands fail to react to mucus tests. He describes, in the gland cells, a disintegration of the protoplasm whereby the body of the cell was converted into a granular, more or less retracting, mass of dead tissue, which appeared to form an emulsion-like fluid which may serve as a source of

nutrition in the earlier stages of development, and which responds to the so-called uterine milk of sheep (Bonnet). He further adds that it is "very doubtful whether the uterine glands possess a secretory function at all." Fujimura,⁶ referring to the morphological changes which he describes occurring in the early stages of pregnancy, records the increase in size of the gland cells as due to the presence of numbers of lipid granules and vacuoles. The cells frequently are detached from the basement membrane and are isolated in the gland lumen. The latter he considers for the most part drained into the uterine cavity, taking in the formation of the so-called uterine milk.

In view of the evidence quoted, it is extremely hazardous except the opinion, so universally held, that the uterine glands exert a secretory function.

Then, their function be not secretory, it is obvious that must account for their presence in some other way. Can

be absorbent in nature? Let us see what evidence there is in support of this view. Leopold⁷ has claimed to have demonstrated the presence of lymph channels and spaces within the uterine mucosa—in other words, he deposed the mucous membrane as to be regarded as a spread-lymph gland permeated by glands and blood vessels. Gan,⁸ whilst not agreeing with Leopold, records the fact that in large mammals a great development of lymphatics takes place on the mucous surface (of the muscular layer) and the mucosa itself, though he states that the uterine glands have no connexion with the lymphatics, either in the pregnant or the non-pregnant uterus, and their functions seem merely suspended in pregnancy.

Everyone who has devoted any attention to the examination of the uterine mucosa at different stages of its development must be familiar with the different appearances of the glands and their immediate surroundings. Within the glands appear not infrequently "gland inclusions." The use of this expression is convenient, for it commits us to no definite view as to their nature; they may possibly be the products of secretion, or the breaking down of the gland epithelium; on the other hand, they may be derived from material which has been introduced from without into the gland lumen, and is there undergoing a process of absorption. That, at certain stages of the menstrual cycle, these inclusions consist of the detritus resulting from the breaking down of the gland wall coincident with the changes associated with the occurrence of the premenstrual stage is admitted, but, on the other hand, there is positive evidence that the gland lumen may contain matter which is derived from without. Thus Marshall⁹ figures a case in which, in a dog in the last stage of recuperation of the mucosa, he observed large numbers of spermatozoa within the cavity of the gland; he further adds that, if copulation has taken place, spermatozoa in great numbers may be observed in the deeper portions of the uterine glands as well as along the edges of the uterine cavity.

So too, in 1909, Kohlbrugge,¹⁰ in his researches on the bat, states that the spermatozoa penetrate into the glands of the mucosa which appear to exercise some chemotactic influence over them. As a result, these glands exhibit cyst-like enlargements which may be mistaken for young blastulae. He points out that the vaginal mucous membrane has no such chemotactic properties, and it is a generally accepted view that spermatozoa soon lose their vitality if detained within the vagina, whilst if they reach the upper parts of the sexual tract they may retain their fertility for lengthy periods. It is known, as for example in the sheep and guinea-pig, that the male ejaculate is thrown directly into the uterus. As a consequence of his observations Kohlbrugge suggests that it may be maintained that a coitus is certainly comparable to an injection of serum.

A detail, regarding which there is much difference of opinion, is the appearance frequently met with in sections of the uterine mucosa of women leading a life of sexual activity—it not unfrequently happens that around the glands there appear spaces separating them from the surrounding stroma. These spaces may well be called periglandular spaces. By a considerable number of histologists these spaces are dismissed as artefacts, due to the irregular shrinkage of the tissues in the process of preparation. That this may possibly be a contributory cause cannot be refuted, but my own observations lead me to believe that the matter cannot thus easily be explained, for in the many mucous membranes I have examined I have found that these spaces are best marked where either the lumen of the tube is dilated or there is evidence of "gland inclusions." Further, it is remarkable that in some membranes submitted to exactly the same hardening processes, there is an absence of these periglandular spaces, whilst in others they are almost the rule. So, too, it is noteworthy that in some sections they occur around some glands, particularly those showing enlarged lumina or exhibiting "gland inclusions," whilst other glands within the same section do not display these periglandular spaces around them. What impresses me most, however, is that in some cases I have seen the periglandular spaces in part occupied by a coagulum, which would seem to indicate that they existed during life and were occupied by a fluid. The fact that they are most pronounced around the glands displaying contents, or a cystic formation, would seem to suggest that they were in some way associated with an absorbent process, an observation in part confirmed by the suggestion of Fujimura already referred to.

If the anatomical and physiological evidence in support of such a view be admittedly unsatisfactory, the same objection can hardly be urged in view of the deductions forced upon us by clinical experience. There is, perhaps, no mucous surface in the whole body so liable to rapid toxic infection as the mucous membrane of the uterus. You are all so familiar with this aspect of the question that I need hardly enlarge upon it. The rapidity with which the toxic effects are induced is clear proof that there exists an absorbent arrangement in close association with a rich lymphatic distribution, which ensures this swift reaction to the injurious influences. What more reasonable than to suppose that the surface and glandular epithelium play an important part in this process?

In summing up what we know regarding the mucous membrane of the uterus, it seems that the weight of the evidence goes to prove that its function is more likely to be absorbent than secretive, and that as such it plays an important part in the animal economy. Let us endeavour to see how this is brought about.

The male ejaculate is composed of an admixture of the secretions of certain glands. These comprise the testis, the vesiculæ seminales, the prostate, and Cowper's gland. For the purpose of this paper we may dismiss from our consideration the last named, for Cowper's gland has its homologue in the female in the shape of Bartholin's gland. Both seem to be employed in the provision of the necessary discharge to lubricate the passages involved in the sexual act.

In respect of the prostate, whilst it may be possible that the rugae developed to such an extent in the upper vaginal wall in the foetus and child may to some extent be homologous with the prostatic anlage in the male, the only evidence we have of a survival of the glandular elements in the female is possibly the paraurethral or Skene's ducts. These are, so far as we know, a mere remnant, and functionless.

So, too, in regard to the vesiculæ seminales. R. Meyer¹¹ states that in the female the persisting Gartner's canal may also form, in the fifth month, an ampulla and a vesicula seminalis, and the ampulla then lies at the level of the

cervix uteri, of the upper part of the portio vaginalis, and extends to the fornix of the vagina and into the uppermost part of the lateral wall of the vagina. Here again in the female the vesiculae are only represented by a vestigial remnant, without any function.

From the above brief statements it appears that in the female there is nothing comparable to the secretions discharged by those important glands in the male.

In many mammals both prostate and vesicular glands are present, but in some—for example, the dog and the cat—the prostate is alone represented. This seems to suggest that, in some cases, nature can dispense with the secretion of the vesicular glands without detriment to the performance of the sexual function, whilst the more frequent combination of the two glands (prostatic and vesicular) seems to point to the advantage of their combined secretions in other instances.

A very brief review of their anatomy and supposed function may be helpful in the consideration of the question before us. The vesiculae seminales, associated, as they are in man, with the vasa deferentia, are oftentimes regarded as overflow cisterns for the storage of the surplus secretions of the testes. The vesicula seminalis, and vas deferens, as you are aware, in man, discharge their contents into the urethra by a common duct, the common ejaculatory duct. This arrangement appears to give support to the view expressed above—that the vesiculae may be regarded as overflow reservoirs. Unfortunately, however, it is open to the objection that in certain animals—hedgehog and guinea-pig—the ducts of the vesicular glands open independently of the vasa deferentia, consequently it is difficult to understand how they can act in the manner suggested. Opinions vary as to the nature of their contents. All agree in recording the presence of a light brownish coloured gelatinous fluid, but there is much diversity of view as to the amount of their spermatozoal contents. It was Hunter who first recorded the fact that in cases where a testicle had been removed, long antecedent to death, the vesicula on the castrated side was as full of secretion as that of the opposite side, an observation since confirmed experimentally on animals by Lode.¹²

It would thus appear that they possess a secretory function independent of the supposition that they act as storehouses for the excess of testicular secretion.

An interesting observation was recorded by S. P. Pittard¹³ as long ago as 1852. In the guinea-pig, where there is an independent duct to the vesicula, he found that on expressing its contents into the urethra there was formed a solid coagulum "as hard and elastic as the cartilage of a ray fish." When, however, at the same time he expelled the contents of the vasa deferentia, he was "highly interested to observe" that the immediate solidification of the mucus did not occur. It appears that comparatively recently (1910) G. Walker¹⁴ has described in the guinea-pig and the rat an accessory gland, which he names the coagulating gland, the secretion of which acts like a ferment upon the secretion of the seminal vesicles, causing it to coagulate. This is interesting, in association with the fact that in the rodents the clotting of the fluid after its entrance into the female passages is supposed to prevent the escape of the spermatozoa and so help to ensure fertilization, though Steinbach¹⁵ states that rats whose seminal vesicles have been removed still retain their desire for copulation, although their fertility is diminished.

Although in the case of the rodents we have this positive evidence of some particular function associated with the secretion of the vesicular gland, we are not much wiser in regard to the influence it may exercise in other animals, for Marshall¹⁶ contents himself with suggesting that "in the majority of animals which possess vesiculae seminales the secretion of these glands serves to dilute the semen, and so assists in providing a fluid medium for the transference of the spermatozoa."

Throughout the mammalia the prostate is met with in a variety of forms as regards structure, position, and relative size. With these we are not immediately concerned, except to point out that they are each associated with the functions they are called upon to discharge, and that these functions may be particularly modified to fulfil the requirements of specific variations. In man alone does the gland completely surround the urethra. There is abundant evidence to prove the intimate association of this gland with the sexual function. If the male be castrated in childhood, the prostate fails to develop; if when adult, the healthy gland then undergoes atrophy. It is common knowledge that in animals, during the rutting season, both testes and prostate enlarge,

and it is noteworthy that in man the gland only begins to attain its full proportions at puberty.

When, again, we come to inquire as to the function of the prostate, we must confess that our knowledge is of the scantiest. Marshall¹⁷ sums it up as follows: "Little is definitely known regarding the function of the prostate, beyond the fact that it contributes additional fluid to the semen."

Luciani¹⁸ does not enlighten us much further, for Fürbringer's view that the prostatic secretion renders the movements of the spermatozoa more active is disputed by Exner and Nagel, who found spermatozoa collected from the epididymis of the guinea-pig as lively as those subjected to the influence of the prostatic secretion. Luciani quotes Walker to the effect that, as a result of his experiments on dogs (1899), he concluded that the prostatic secretion stimulates the spermatozoa to movement by diluting the liquid; but it contains also nutritive substances for the spermatozoa, thus explaining the fact observed by Steinbach that the movements of the spermatozoa are prolonged for a greater length of time when they are immersed in the prostatic secretion.

In regard to the manner in which the secretion is retained within the prostate, Griffith¹⁹ draws attention to an interesting point. He explains that the secretion is stored in those parts of the gland lumina which are nearest the urethra, and consequently these collections are expelled during the sexual act by the contraction which begins at the distal end of the non-striated muscular sheath which surrounds each tubule in its whole length.

To these suggested functions of the prostatic secretion must be added the observation that the increase in bulk of the ejaculate thus effected will mechanically facilitate the action of the muscles concerned in its expulsion.

As concerns the nature of the secretion itself little need here be said. It is described as a milky, slightly alkaline fluid, containing protein, but free from mucus. In the dead body it contains a great number of crystals of spermine (which are absent in the living) to which is due the characteristic odour of the semen. The biochemical analysis of the ejaculate is as yet, so far as I know, almost entirely confined to a study of the spermatozoal contents; the difficulties of isolating the different secretions are naturally great, so that we are treated rather to a consideration of the whole than an isolated analysis of each contributing factor. It is not with this aspect of the question that I wish to deal, even were I competent, but with certain general considerations which must have attracted the notice of most observers.

According to Marshall, the average amount of the ejaculate in man is 5 grams. What becomes of it? Even admitting the loss of a considerable portion of it by escape from the vagina, there must remain a surplus which is passed higher up the genital tract. We are not concerned with the mechanism whereby this is effected, be it by the method suggested by Heck²⁰ in which, from observations on a prolapsed uterus, he had reason to believe that an aspirating effect was exercised by the uterus—or possibly through the agency of some chemotactic properties on the part of the spermatozoa.

The fact remains that a considerable part of the ejaculate reaches the uterus. We have already seen that in some animals, such as the sheep and guinea-pig, the ejaculate enters the uterus directly. What becomes of it? We have already shown that, in the present state of our knowledge of the functions of the uterine mucosa, there is as much if not more reason to believe that the uterine glands act as absorbing agents, as that they exercise a secretory function. The observations of Kohlbrugge and Marshall on animals, to the effect that they have seen spermatozoa within their lumen, is evidence of a kind which cannot be disregarded. I confess I have not seen anything that I could identify as spermatozoa, but Kohlbrugge and Marshall's figures seem to leave no doubt on the matter. If, then, spermatozoa may be got rid of by entering the glands it follows that they must be accompanied by some of the fluid in which they are immersed—namely, the secretions of the vesiculae seminales and prostate. Having once gained entrance, it is not difficult to realize how they may be absorbed just as we know from clinical experience how easily infection takes place through the absorption of toxic products. I wish to emphasize this point, and to make clear the issue. One only of the many thousands of spermatozoa which enter the genital tract is required for the purposes of fertilization, and it by no means follows that each or any ejaculate provides the required spermatozoa. It is clear, therefore, that a considerable bulk of them never

serve the purpose for which they were designed, but die and disappear. At the same time it must be admitted that the spermatozoal content of the semen forms but a small proportion of the ejaculate, the bulk of which is made up of the secretions of the vesiculæ seminales and the prostate. We have already seen how this increase in the bulk of the ejaculate may favour its expulsion, but as yet we have not had any satisfactory explanation why two glands of separate origin and structure should be required for this purpose. The reasonable way of looking at the question is to suggest that the glands concerned furnish secretions which serve different purposes. But, excepting the function exercised over the secretion of the vesiculæ seminales in the rodents by the presence of a coagulating gland, and the subsequent formation of a vaginal plug, there is no suggestion that can be offered, other than that in some way the secretions of the vesiculæ seminales and the prostate tend to maintain the vitality and activity of the spermatozoa, and to supply them with some appropriate nutriment; also, by dilution, they increase the bulk of the ejaculate. These conclusions are, in the main, a confession of our ignorance. At present they hold the field for lack of anything better.

In considering the question as it applies to man, it must be pointed out that in his sexual relations man is not controlled by such seasonal conditions as regulate the congress of the sexes in other animals. There may have been a time when such restrictions were imposed on him, and even now, in some races, there is evidence of a periodicity determined by local circumstances, but under existing conditions the bulk of mankind is at liberty to indulge in sexual congress throughout the entire length of their sexual life, except during the occurrence of the menstrual flux, and this is not always a deterrent.

It happens frequently, therefore, that sexual union may occur when no ova are present to be fertilized. I do not intend here to discuss the question of ovulation in respect of its periodicity or association with the menstrual cycle. I am alone concerned with the fact that insemination may occur for periods, undetermined, without the female being impregnated, in other words, without an ovum being fertilized. It is to this aspect of the case that I wish to direct your attention.

Is any change effected in the female by the act of insemination apart from the specific act of fertilization? Your experience must provide the answer.

I fancy that it is within the knowledge of most of you that marriage has resulted in greatly improved health in the case of women who, prior to their indulgence in normal sexual intercourse, were of sickly habit and imperfect physique, and this without the necessity of pregnancy intervening. I would be inclined to regard the pregnancy as the accident that may happen, not as the forceful influence which works to bring about such profound changes in the economy of woman, both as regards her functions and her psychic outlook. That some such change occurs at the first act of sexual congress is an old-standing belief. In one of the poems of Catullus (*Carmina*, lxxiv, 11, 376-378) the following lines occur:

Non illam nutritrix orienti luce revisens
Hesterno collum poterit circumdare filo,

which being literally translated, reads: "The nurse revisiting her charge at daybreak shall not be able to encircle her neck with yesterday's thread." A footnote appended in the edition consulted reads as follows: "A thread was measured round the neck of the bride before night, if next morning her neck had not become large enough to prevent the thread from reaching right round, it was thought a sure sign that the marriage had not been properly consummated." The application of this test is an old custom which, according to Havlock Ellis,²¹ still survives in the South of France.

What is the significance of this custom? It is well known that the thyroid gland is intimately associated with the sexual system, and that it responds, by increase in size, to pregnancy, and in some cases undergoes periodic enlargement corresponding to the menstrual cycle. That it often increases in size at the onset of puberty is common knowledge, but the suggestion in the above quotation, and the practice of the ancient custom associated with it, is that the change involved in the increase in size of the thyroid—for it is this that leads to the increase in the diameter of the neck—is rapidly and apparently directly induced by the first insemination. If this be so—and there is apparently no reason why this belief should not be confirmed by actual observation—then there is absolute proof that the ejaculate contains

other ingredients than those alone concerned with fertilization. May there not be some hormone or endocrine secretion, call it what you will, which, by rapid absorption through the tissues of the female, sets agoing, through the agency of the thyroid, the complex mechanism involved in the elaborate preparations of the sexual system to meet its reproductive obligations? The matter is surely worthy of investigation. McCarrison²² briefly refers to this aspect of the subject when, dealing with the life-history of the thyroid apparatus, he says: "The sexual act and marriage in both sexes increases the gland's activity, and it is known to swell in consequence, a fact well known to primitive races."

Sir W. Arbuthnot Lane²³ makes many suggestive observations regarding the disabilities and compensations entailed by the reproductive function in the female. As to the part played by the thyroid gland, he notes how its enlargement is accentuated by intercourse and by pregnancy, and is of opinion that it alters with the intensity of the sexual appetite. As regards the sexual life of woman, he dwells on the necessity of considering two factors: One is the action of the prostatic secretion on the woman, and the other is that of pregnancy. He regards the prostate as possessed of a double function—an internal, the effect of which on the man is to act as a powerful stimulant; an external, the action of which on the woman is very far-reaching and active in its results. He recites his experience in cases of chronic intestinal stasis in the female, to the effect that frequently the condition is associated with breasts which he describes as "hard and nobbly." If, says he, the prostatic secretion is in sufficient quantity the hardness does not develop, or if it already exists, it will subside or disappear altogether.

Now all these observations appear to give support to the view already expressed, that the male ejaculate possesses other properties than those directly associated with the male fertilizing elements. As yet, owing to the fact that hithert zoologists and anatomists have mainly been concerned with the phenomena associated with the congress of the germ and sperm cells, and their consequent results, it happens that relatively little attention has been directed to the other potentialities of the male secretions so far as their effect on the female is concerned.

I only know of one other piece of evidence having a bearing on the question. I give it for what it is worth, but I have been informed by one whose opinion I respect that among musicians it is recognized that the female voice never attains to its full pitch of excellence until marital relations have been established.

Possibly within your own personal experiences there may be other observations which have a bearing on the question. It is with this idea in view that I have addressed you to-night in order, if possible, to acquire further information regarding a subject about which our views are still uncertain and defined. There is an aspect of it which one approaches with some hesitation. So far we have considered the question: the assumption that the congress of the sexes is effected under normal and natural conditions, and no account has been taken of the use of artificial checks to prevent conception. It does appear, however, that the employment of such methods, whilst preventing fertilization, may also be the means of depriving the female of certain secretion which may exercise a far-reaching influence on her economy. Amongst obstetricians I have heard the opinion expressed that indulgence in these practices is accountable for some of the neuroses from which modern woman so frequently suffers. As a rule, we cannot interfere with the normal courses of nature without some consequent evil result. Is this not an instance in which, for some apparent gain one direction, woman pays the penalty?

It befits us to weigh these matters wisely and well, for surely the problem is one which is worthy of our most serious consideration.

Observations

ON

SECRETION INTO THE STOMACH AND DUODENUM:

WITH SPECIAL REFERENCE TO DIABETES MELLITUS.

BY

T. IZOD BENNETT, M.D., M.R.C.P.,

ASSISTANT PHYSICIAN, MIDDLESEX HOSPITAL; DEIT MEMORIAL
FELLOW FOR MEDICAL RESEARCH;

AND

E. C. DODDS, M.R.C.S., L.R.C.P.,

ASSISTANT IN BIOCHEMISTRY, BLAND-SUTTON INSTITUTE OF PATHOLOGY,
MIDDLESEX HOSPITAL.

(From the Bland-Sutton Institute of Pathology, Middlesex Hospital.)

THIS communication is not meant to be of more than a preliminary character, the data on which it is based are insufficient for conclusions of any final nature to be drawn from them; but our results point in a direction so different from that of the majority of existing views concerning diabetes mellitus, and at the same time are so readily brought into line with existing data concerning the disease that we feel it advisable to bring them to the immediate notice of the profession.

Some time ago one of us (E. C. D.) drew attention¹ to the inconstancy of the alveolar CO_2 tension in any individual in the course of the day. Samples of alveolar CO_2 being collected by the Haldane-Priestley method and analysed by

the Haldane apparatus at successive intervals, the mean tension of an expiratory and an inspiratory sample was calculated; the result of these observations may be summarized as follows:

FIG. 1.—Curve of alveolar CO_2 tension to show the continuous level when fasting, interrupted by a rise, followed by a fall, on taking a meal.

2. If such a fasting subject be given a meal the CO_2 tension is found to rise, the tension increasing usually about 3 to 5 mm., reaching its highest point during the first hour; it then regains the original level and proceeds to fall below it to a depth of about 3 to 5 mm., finally rising once more to the fasting level, which it regains about two to two and a half hours after the meal; it then remains at this level until the next meal be taken (v. de Fig. 1).

FIG. 2.—Curve of alveolar CO_2 tension following a meal, from a patient whose stomach had been almost completely excised.

that these secretions must be derived from the blood supplying the glands of the alimentary canal, it becomes clear that the outpouring of HCl by the stomach must tend to shift the reaction of the blood to the alkaline side. Now the tendency of the body as a whole is to maintain the reaction of the blood at a constant level, and a rapid method of doing this is to retain in the blood stream the volatile acid CO_2 in proportion as HCl is lost; such retention of CO_2 will result in an increased tension of the gas in the blood and hence a rise in the tension of alveolar CO_2 .

Similarly the evolution of alkali during later stages of digestion will occur at the expense of the blood stream, where less CO_2 will now be necessary for the maintenance of neutrality, and hence there will be a lowered tension of CO_2 , both in blood and in alveolar air.

That the rise of CO_2 tension following a meal does correspond very exactly to the extent of gastric secretion of acid

we were able to establish by a series of observations on healthy men, it being shown² that those with marked gastric hypersecretion showed an enormous rise of CO_2 tension, whilst those with no secretion of HCl at any time gave no rise in CO_2 tension whatever; the contrast between a case with complete achlorhydria and one with secretion slightly above the average is seen in Fig. 3.

It has been more difficult to establish the exact significance of the drop in CO_2 tension in the later stages of digestion, but by introducing a modified Einhorn's tube into the duodenum we have been able to demonstrate that the direct introduction of food in this situation is, in the normal man, immediately followed by a sharp fall in alveolar CO_2 tension.

Such an experiment is illustrated in Fig. 4, which shows the immediate drop in CO_2 tension produced whenever food is injected into the duodenum (A and B); when, however, the tube was drawn

FIG. 4.—Curve of alveolar CO_2 tension to show the effect of direct introduction of food into duodenum: at points A and B food was injected through duodenal tube; at point C the same process was repeated after tube had been pulled up into stomach.

up into the stomach and the food introduced into that organ (C), a rise, followed by a fall, such as is seen after an ordinary meal, was produced.

These experiments, a full account of which will be found in the forthcoming number of the *Journal of Physiology*, have, when examined in conjunction with the curves obtained from normal subjects and those with achlorhydria, confirmed our belief that the fall in CO_2 tension which occurs in the later stages of digestion corresponds with the outpouring of alkali when food has traversed the pylorus.

The alkali secreted into the small intestine is of threefold origin, coming from:

1. The liver.
2. The mucous membrane of the intestine.
3. The pancreas.

The secretion of bile is considered to be a continuous process, and, such being the case, cannot periodically affect the CO_2 tension; of the other two factors the work of Boldyreff³ shows that the pancreatic secretion is by far the more important as a source of alkali. That such is the case is indicated by an observation which was obtained from a patient proved by exploratory laparotomy to have chronic pancreatitis (a fuller account of this case will appear in our paper in the *Journal of Physiology*); the curve of alveolar CO_2 tension is shown in Fig. 5, and it will be seen that the

FIG. 5.—Curve of alveolar CO_2 tension from subject suffering from chronic pancreatitis (at 10.30 a.m. and 1.30 p.m. contrasted with average normal subject).

drop in tension is notably diminished when compared either with an average man, or with a case of achlorhydria.

Working with normal human subjects, we have found that the respiratory response to food can be affected by the local application of atropine solution to the gastric or duodenal mucous membrane. Thus if the gastric mucosa be washed with a weak solution of atropine the secretion of HCl, as shown by aspiration of samples of the gastric contents, can be abolished, and we have found that, when a test meal is given after such lavage, the rise in CO_2 tension does not occur, although the inter fall in tension still takes place. By means of the duodenal tube we have been able to apply a similar solution of atropine to the mucosa of the duodenum, and in this experiment we found that we had succeeded in abolishing the response which normally follows the entry of food in this situation.

The experiment is illustrated in Fig. 6. The duodenal tube having traversed the pylorus and the fasting subject having a constant tension of O_2 , food was injected through the tube at the point marked A, the result being a typical fall in tension. At the point B the duodenum was washed with atropine solution and the

FIG. 6.—Curve of alveolar CO_2 tension to show effect of atropine when applied to duodenal mucosa. A Food injected direct into duodenum with normal response. B Weak solution of atropine injected into duodenum through tube producing a rise in the fasting level of O_2 (at point marked "B" difference between samples of alveolar air was too great to allow of accurate measurement). C Food injected into duodenum with no response. D Food injected into stomach causing gastric response without subsequent fall.

CO_2 tension, after fluctuations, assumed a constant, though higher, level once more. At the point C food was again injected into the duodenum, but this time it produced no response whatever; when, however, the tube was pulled up into the stomach and food injected into that viscus at the point D, a gastric rise of tension at once occurred without any fall at a later period.

This, with other experiments with atropine, to be published shortly, bears out and amplifies the local effects of that drug which one of us has referred to in a previous paper.¹ These effects may be summarized as follows:

1. Gastric lavage with atropine solution diminishes or abolishes the secretion of acid by the stomach.
2. Gastric lavage with atropine solution can abolish the rise of alveolar CO_2 tension which normally occurs when food enters the stomach, it does not affect the fall of CO_2 tension which occurs after the food has traversed the pylorus.
3. Gastric lavage with atropine solution causes the fasting level of alveolar CO_2 tension to fall to a lower level.
4. Duodenal lavage with atropine solution can abolish the fall of alveolar CO_2 tension which occurs when food is injected into the duodenum, it does not affect the rise of CO_2 tension which occurs on the entry of food into the stomach.
5. Duodenal lavage with atropine solution causes the fasting level of alveolar CO_2 tension to rise to a higher level.

It here becomes necessary to discuss the meaning of the change in the fasting level of CO_2 tension summarized under headings 3 and 5.

Carlson, in his admirable study, *Hunger in Health and Disease*, has drawn attention² to the continuous nature of gastric secretion; aspiration of the fasting stomach will frequently yield appreciable quantities of juice containing HCl; this is a product of that continuous gastric secretion which goes on in the healthy man at all times, being interrupted at intervals by a much greater flow in response to the approach or entry of a meal. As such a secretion of acid must be made at the expense of the blood stream, it will entail the constant retention in the blood of a corresponding amount of CO_2 ; if, then, by means of atropine, the temporarily checked, its arrest will be shown by a lessened retention of CO_2 , and hence by a lowering in the fasting level of alveolar CO_2 tension.

Our experiment, illustrated in Fig. 6, shows that a converse phenomenon occurs when atropine is applied to the duodenal mucosa; there is an immediate rise in the fasting level of alveolar CO_2 tension. We would suggest the following explanation of these experimental facts:

1. Gastric secretion is known to occur continuously, even when the stomach contains no food; arrest of this continuous secretion will very naturally lessen the continuous loss of acid from the blood stream, and so will lower the fasting level of alveolar CO_2 tension.
2. It is known that salivary and gastric secretion continue even between meals; it is probable that pancreatic secretion continues in a similar manner.
3. The rise of alveolar CO_2 pressure to a new and higher fasting level which follows atropinization of the duodenum is the result of the arrest of such continuous secretion of alkali into the duodenum.
4. Further, it may be logically deduced from the above that the fasting level of alveolar CO_2 tension in any subject represents a balance between the continuous loss of acid via the stomach, and the continuous loss of alkali via the duodenum. That some such explanation would be arrived at we had suggested in our previous paper, wherein we drew attention to our observation that cases with an excessive secretion of gastric HCl have a high fasting level of alveolar CO_2 tension, whilst in those with achylia gastrica the CO_2 tension is at a low level.

It was this deduction that led us to make further investigation into the problem of diabetes mellitus.

The clinical application of alveolar air analysis in diabetes is due chiefly to the work of Beddard, Pembrey, and Spriggs, who showed that the onset of ketosis and coma might be diagnosed at an early stage by the lowering of the percentage, or tension, of CO_2 in the alveolar air; this effect has been explained by the presence of aceto-acetic acid in the blood stream, which replaces a certain amount of CO_2 in such cases, a view with which we are in entire agreement; at the same time we have been impressed by the fact that many diabetics, even when exhibiting no sign of ketosis, have an unusually low level of alveolar CO_2 tension. Gastric analysis on such cases has not, in our experience, shown an abnormally low secretion of gastric HCl, and the question was raised in our minds as to whether this lowering of alveolar CO_2 tension might not possibly be due to a hypersecretion of alkali by the pancreas.

We have now had the opportunity of examining six cases of severe diabetes mellitus, and we have found that in all of them the curve of alveolar CO_2 tension following a meal is of a type not seen in any other disease which we have investigated. The following is a typical example:

Case 1.—Male, aged 50. Admitted to the Middlesex Hospital in June, 1921, under the care of Dr. A. F. Voecker. Wasting, thirst, and polyuria. Glucose present in large quantities in the urine, aceto-acetic acid also positive. Reduction of the diet gave slight improvement only. Gastric analysis on July 4th, 1921, showed a secretion of HCl by the stomach slightly lower than the average normal picture (Fig. 7; alveolar CO_2 estimation following a test

FIG. 7.—Curves of alveolar CO_2 tension and of gastric HCl from a severe case of diabetes mellitus. The gastric HCl is rather below the average normal amount; the CO_2 curve shows a small preliminary rise followed by a fall far greater than that seen in the normal subject.

meal on July 5th showed a slight gastric rise followed by a fall of 7 mm. Hg, the tension not returning to the fasting level for more than an hour and a half. In spite of careful dieting this case showed only a moderate degree of improvement on discharge four weeks later.

The results of alveolar CO_2 estimation in this and subsequent cases of diabetes are shown plotted together in Fig. 8, a typical curve from an average healthy subject being plotted in the same figure for comparison. All were diabetics of the severe type, brief clinical notes of their condition being as follows:

Case 2.—Male, aged 55. One month's history of thirst, weakness, and polyuria. Admitted under care of T. I. B., August, 1921. On admission had pyrexia and signs of early diabetic coma,

urine contained much glucose, acetone, and aceto-acetic acid. Condition improved slightly, but pyrexia continued; signs at bases of both lungs. Ten days later patient became comatose and died. *Post mortem* examination showed purulent prostatitis, septic bronchopneumonia, and slight macroscopic changes in pancreas, sections of which are being sent.

Case 3.—Male, aged 25. Admitted under Dr. R. A. Young, September, 1921, for thirst and loss of weight. Much sugar, acetone, and aceto-acetic acid in urine. Patient refused strict diet and was eventually discharged unimproved.

FIG. 8.—Curves of alveolar CO_2 tension from a series of cases of severe diabetes mellitus; an average normal curve is shown for comparison. In this figure the readings recorded at the moment of the meal are, in Case 2 and Case 3, assumed; several readings were taken in each case before the meal, but not actually at the last moment before giving it. The normal curve is the average of a series of observations.

Case 4.—Female, aged 25. Severe diabetes for four years. Has been sugar-free on diet of less than 1,000 calories per diem for over a year; during last three months tolerance has fallen lower, and she now passes small amounts of sugar on lowest diet compatible with N-equilibrium. No acetone or diacetic acid in urine. Blood sugar curve typical of diabetes mellitus.

A few milder diabetics rendered sugar-free by dieting and having now a fair sugar tolerance, whom we have been able to investigate, have shown curves of alveolar CO_2 not differing from the normal picture seen in health.

If the interpretation which we have given above of the normal curve of alveolar CO_2 tension following a meal be correct, the extreme and protracted drop in tension seen in severe cases of diabetes indicates that in this disease there is hypersecretion of the pancreas. Now, it has been pointed out by Allen and others that the internal secretion of the pancreas is inversely proportional to its external secretion, and, on that hypothesis, the success which has attended the treatment of the disease by the principle of "alimentary rest" is explained. We would suggest that, in severe cases of diabetes, the external secretion of the pancreas is of an extreme degree, analogous to the hypersecretion of the stomach seen in patients suffering from Reichmann's disease. Alimentary hypersecretion is a phenomenon which is exceedingly difficult to demonstrate by any direct method; in the case of the stomach it can be done by accurate measurement both of the amount of juice aspirated at varying periods, and the degree of concentration of this juice; there being no convenient sphincter below the pylorus, it is impossible to collect more than small samples of the pancreatic juice in man, but we are at present devising means of confirming our findings by some such direct method. We wish in the meantime to draw attention to our observations, and to note that our belief that they indicate a condition of pancreatic hypersecretion is not in discord with existing clinical and laboratory data, even though the conception itself be a novel one.

The parallelism between these curves of CO_2 tension and the curve of blood sugar commonly seen in a diabetic is a fact which must strike anyone familiar with the latter, and we hope in a later paper to bring forward further evidence as to this. The comparative rarity of macroscopic or microscopic evidence of gross pancreatic disease in cases of diabetes seen *post mortem* has long troubled students of this disorder,

and has made it almost impossible to harmonize theory with Minkowski's experimental production of the disease by pancreatectomy; we feel that the present observations supply valuable evidence towards the elucidation of this problem.

As to treatment our experiments with atropine suggest that a considerable degree of control over pancreatic activity may be acquired by the direct application of the drug to the duodenal mucosa; we are not yet in a position to produce clinical evidence in support of this suggestion, but hope to do so at a later date.

We would, in conclusion, express our thanks to our colleagues and co-workers at the Middlesex Hospital for their valuable help and permission to investigate cases under their care. The respiratory observations here recorded form part of a report to the Medical Research Council; the expenses of one of us incurred in this research have been partly defrayed by a Government grant made through the Royal Society.

SUMMARY.

1. The variations in alveolar CO_2 tension after a meal depend, in a subject at rest, on the secretions of acid and alkali into the stomach and duodenum.
2. Confirmation of this is given by the curves of alveolar CO_2 pressure from subjects with varying degrees of gastric secretion, or with pancreatic insufficiency.
3. Further confirmation is supplied by the results of experimental introduction of food direct into the duodenum.
4. The application of atropine to the mucosa of the stomach or duodenum appears to arrest the secretion of acid or alkali into the organ to which the drug is applied.
5. The writers believe that, like salivary and gastric secretion, pancreatic secretion must be a slow, continuous process interrupted by a more vigorous flow whenever food traverses the pylorus.
6. The fasting level of alveolar CO_2 tension in any subject represents a balance between the continuous loss from the blood stream of acid via the stomach, and alkali via the pancreas and duodenum.
7. Cases of severe diabetes frequently show a low fasting level of alveolar CO_2 tension even when no ketosis is present.
8. Cases of severe diabetes investigated by the writers have, after a test meal, shown a fall of alveolar CO_2 tension greater than that seen in any other condition so far examined.
9. It is suggested that this is due to a condition of hypersecretion of the pancreas, analogous to the gastric hypersecretion seen in cases of Reichmann's disease.

HEMIPLEGIA IN A YOUNG CHILD, FOLLOWED LATER BY LOCOMOTOR ATAXIA.

BY

WILLIAM CALWELL, M.D.,

PHYSICIAN TO THE ROYAL VICTORIA HOSPITAL, BELFAST.

The explanation of the rather complicated signs in the following case is probably as follows. The patient inherited syphilis, and developed a vascular lesion at the base of the brain when 3 years old, probably a syphilitic thrombosis in an artery at the left internal capsule. This gave rise to the right hemiplegia and aphasia at the time, and to the slight diminution of size and strength of the right side, which is the more marked where there is the greater differentiation of function—that is to say, most in the hand, least in the trunk—and to the right Babinski, and to the increased jerks in the right arm. A couple of years ago locomotor ataxia set in, and she developed the droop and the diplopia; we have no proof that the Argyll Robertson pupil, the inequality of the pupils, and the loss of lence-jerks developed at the same time, but we surmise it.

A girl, aged 17 years, was admitted to the Royal Victoria Hospital, Belfast, on August 19th, 1921, under Dr. Calwell. Her father had died, aged 45, from angina pectoris. She is the only child alive; four sisters and one brother died before two years of age; two were premature, one died age 17 weeks and the other aged 8 months. Her personal history, as given by the mother, is that she had a sudden attack of right-sided paralysis with aphasia when 5 years old; she recovered her speech in two weeks and the use of the arm and leg was regained in a year. Ever since she has had a "halt" in her gait, and no spring in the right foot; she says the right side is weaker than the left.

On admission, the various systems were found normal, except as follows: The right upper and lower extremities are smaller than the left, and this holds both as regards length and circumference; the difference varies from one 1/4 inch to 1 1/2 inch. It is more marked in the arm than in the leg, and most marked in the hands; the left metacarpus measures 1 1/4 inches round, the right only 5 inches. No difference is seen in abdomen, buttock, or back; the left knee-joint is slightly swollen, but the x rays show no bony change.

The right foot is pes cavus with some equinovarus; there are some slight athetoid movements of the right foot which interfere somewhat in taking the reflex. The gait is not characteristic; she lifts the right foot as in high stepping, gives it a slight indefinite shake, and brings it down awkwardly more on the toes; the left foot comes down a little on the heel.

With reference to her reflexes, there is no plantar reflex on the left; there is a trace Babinski type on the right, but obtained satisfactorily only once every three or four times; no knee nor ankle jerks are present in either. Co-ordination and topognosis with feet is poor, slow, uncertain, and clumsy. In the upper extremities, supinator, triceps, and biceps jerks clearly more marked in right, indeed exaggerated; co-ordination and topognosis is good with both. Romberg is doubtful, although the patient was uncertain in standing and bending with her eyes closed. The sensory system is normal, the speech normal.

In the eyes there is ptosis of left lid, sometimes marked, sometimes slight; there is paralysis of the left external rectus; fine lateral nystagmus is present in the right eye when looking upwards and outwards. The discs are normal and sight good; there is diplopia when looking to the left, and in the left eye the field of vision is slightly contracted. Argyll Robertson pupil is present in both eyes; the left pupil is larger than the right. A Wassermann test of the blood was returned from the laboratory as double positive, by both Harrison's and Fleming's methods.

It is interesting to notice the presence of the Babinski reflex and the loss of knee-jerk in the same limb; this latter reaction depends on the condition of the tone of the muscle. If the tone is marked we have a brisk reaction; if excessive we have a clonus; but in this case where we would expect an excessive tone as we have in the arm, the tone is lost owing to the syphilitic affection of the posterior roots, containing the sensory fibres of tendon and muscles, and so we get loss of both knee-jerks. A weak point here is the absence of any history of lightning pains.

A plantar reflex has the following explanation: a family group of congeries of cells in one or two adjacent segments of the spinal cord has in time past been so often subjected to the same stimulus, and called upon to react in exactly the same manner that the total forms an organic whole, and the reaction is automatic or "a reflex." The cells in the lumbar enlargement are influenced by not only the cortical fibres through the crossed and uncrossed pyramidal fibres, but also by the descending tecto-, rubro-, cerebello-, and Deiters'-spinal fibres. When the influence of the cortical fibres is removed by a lesion, say in the internal capsule, the other descending fibres have full sway and the type of reflex goes still further back, say from that of our arboreal ancestors to that of our still more remote ancestors of the plains, and so we get a dorsi-flexor or Babinski instead of a plantar flexor reflex. This reflex does not depend on a tone condition, and so in this case it is retained.

The patient has greatly improved in general health and weight since admission to hospital; she feels stronger and says she has more control of the ptosis and locomotion. She has received one injection of 0.3 gram and twelve of 0.45 gram of novarsenobillon; but the Wassermann is still positive.

ASTHMA AND THE RADIUM MENOPAUSE.

BY

J. N. MACBEAN ROSS, M.C., M.D., F.R.C.S. EDIN.

With a Note by

SIR HUMPHRY D. ROLLESTON, K.C.B., M.A., M.D., F.R.C.P.

WHILE it is frequently found that women with an asthmatic personal or family history are peculiarly liable to develop the disease in a more severe form during the period of the menopause, there appears to be no case on record of exceedingly intractable asthma due, at any rate in part, to the artificial completion of the menopause by the introduction of radium into the uterine cavity.

So many instructive conclusions and interesting surmises can be drawn from the following case that it appears worth while to publish the details.

The patient, Mrs. X., had lived in the same house for three years, and during that time had not suffered from asthma. She is now aged 47 years. There is no asthmatic, unstable,

or neurotic family history. In 1906 she had the radical operation performed on both maxillary antra for acute supuration in those cavities. In 1909 she had an attack of asthma, which was the only one prior to her present illness. In October, 1920, she developed a peculiar mental condition, which Sir Maurice Craig diagnosed as being due to cerebral anaemia caused by excessive monthly loss of blood. On his advice the menopause was artificially induced by the introduction of radium into the uterine cavity. This radium was lent by Dr. N. S. Finzi and the dosage worked out by him. In ten days she was mentally quite normal and menstruation has permanently ceased.

As soon as she commenced to resume partially her ordinary life a purulent secretion appeared from both antra, accompanied by exceedingly troublesome asthmatic attacks. At that time I considered the asthma to be purely an anaphylactic symptom caused by organisms from the nasal discharge, to which organisms or their products the patient was hypersensitive. On this assumption I asked Mr. Philip Franklin to put her nose thoroughly in order. He straightened the septum, removed a large spur of bone, scraped away some carious bone from the ethmoidal region on the right side, and enlarged the openings into both antra to allow of more adequate drainage of the cavities. At the time of operation Sir Kenneth Goadby made a bacteriological examination of the sputum and swabs from the right and left antra and high up in the nasal fossa. He reported that the sputum contained large numbers of pus cells and long chain streptococci, whilst both nasal and antral swabs showed large numbers of streptococci and also Gram-negative bacilli (probably Friedländer's).

An autogenous vaccine was made, and she was given twelve progressively increasing doses. No improvement was noticed. Asthma was practically continuous; bronchitis was marked at both bases; the patient was losing weight, could get no rest by day or night, and was rapidly going downhill.

During this time I made exhaustive trials of practically every known medicine, inhalation, nasal spray, hypodermic injection, and powder which had any reputation whatsoever in controlling asthmatic attacks, but none had the slightest beneficial effect. At that stage I was still hopeful that, the nose being now in excellent order, the vaccine treatment would ultimately be curative. This belief was bolstered up by the fact that the eleventh and twelfth injections were followed by a generalized urticaria, especially round the site of injection, and these two injections definitely excited two particularly severe asthmatic attacks. This was taken to imply that the patient was undoubtedly sensitive to the products of the nasal discharge, and consequently it was logical to continue the vaccine, though, of course, in smaller doses until tolerance was obtained.

In August, 1921, Sir Humphry Rolleston saw the patient in consultation with me. His opinion, now proved to be entirely accurate, was that, whereas the nasal discharges were certainly the main factor in the production of the asthma, some other factor must also be present, in view of the fact that the vaccine was not curative. Feather pillows, dogs, cats, eggs, etc., were all in turn excluded, and the patient was going from bad to worse.

On October 2nd her condition was extremely critical. The asthma was perpetually present both day and night, and was most distressing both to herself and to her relations. The pulse was weak, irregular, and almost imperceptible at times; the temperature ran up to 102° F., and a fatal issue appeared imminent. Dr. Canti saw her in consultation with me, and made an exhaustive pathological examination, including even a spectroscopic examination of the blood, but no light could be thrown on the subject. Oxygen inhalations and hypodermic injections of strychnine were urgently necessary.

On October 10th, thinking that the menopause might be the additional factor I had been looking for the patient was given by the mouth ova-mammoid compound (British Organotherapy Company, Ltd.), consisting of ovarian extract 1 grain and mammary gland extract 1 grain, four times daily. The result was as unexpected as it was striking. On the following day the asthma and bronchitis, which for a year had never been absent, were markedly improved, and by the third day the asthma had entirely disappeared with the exception of a very minor attack in the early morning. The treatment was persevered with and she improved progressively. She is now to all intents and purposes cured.

During the whole course of treatment neither peptone nor serum was given.

Conclusions.

1. One application of radium to the uterine cavity is sufficient to complete the menopause. Hence operative procedures are unnecessary purely for this purpose.
2. The method is not free from distressing or even dangerous results.
3. Just as in oöphorectomy and panhysterectomy so also in all methods which suddenly induce the menopause ovarian extract should be given as a routine proceeding.
4. Many illnesses at the time of the menopause may be due, either wholly or in part, to ovarian insufficiency, and in all such illnesses ovarian extract should be given a trial.
5. Asthma may be due to a deficiency in one of the internal secretions, and this may possibly account for the success of adrenaline in certain cases, of pituitrin in others, and of ovarian extract in this case.
6. In asthma two factors may be at fault and both must be treated to obtain a satisfactory result.

Note by SIR HUMPHRY ROLLESTON.

Dr. MacBean Ross's account of this remarkable case is so clear that little remains, except, perhaps, unfruitful speculation as to the relation between the administration of the ovamammoid compound and the cessation of the grave asthmatic state.

That the beneficial effect of this preparation was solely due to suggestion seems improbable, because other forms of treatment just as likely to produce such an influence had proved futile. As the ovamammoid preparation was given by the mouth and not hypodermically it can hardly be argued that it acted, like the intramuscular or intravenous injection of peptone (Auld), as a non-specific desensitizer. Lastly, it is difficult in the present state of our knowledge to say that the sudden production of ovarian insufficiency caused, by means of the resulting upset of the endocrine balance, a metabolic asthma; it is just conceivable that from sudden withdrawal of an ovarian internal secretion the thyroid secretion might become relatively excessive and so render the central nervous system susceptible to stimulation by the "foreign" protein provided by the aural suppurative, with the result that asthmatic manifestations followed.

Such speculation, though attractive to the speculator, is not based on the proper basis of experiment, but it renders all the more desirable investigation of cases of asthma occurring after the artificial production of the menopause.

A NOTE ON THE TREATMENT OF SQUINT.

BY

HENRY SMITH, C.I.E., LIEUT.-COLONEL I.M.S.,
LONDON.

UNDER the term "squint" I include all non-paralytic errors of muscle balance of the eye. There has been a large amount of interesting work done on the anatomy of the extrinsic muscles of the eye, and on operative procedures to correct errors of muscle balance. I recently attended discussions on these issues in the United States of America. The only comment I made during these discussions was that we would do well to shake ourselves free from all that had been done and revert to first principles.

From the mechanical point of view it seems to me that nature has inserted the extrinsic muscles of the eye in such a position that each shall obtain the same maximum leverage and that this leverage shall be constant whatever the position of the eye. That is to say, the recti muscles are inserted well in front of the equator, the equator or any point in front of it being equally the position of maximum mechanical advantage. Hence the retarding of any tendon would be mechanically unsound. From the physiological point of view it is well known that the force with which a muscle contracts increases with the degree to which it is stretched within limits before contraction. Tendon tucking or advancement stretches one of the muscles of the eye and introduces a factor which cannot be gauged.

From the surgical point of view any cutting operation leaves scar tissue which is subsequently liable to contract, and none is more likely to do so than tendon tucking. The latter almost invariably means muscle tucking, hence it can be seen that no operative procedure can pretend to anything like scientific accuracy. In fact, in almost all cases the final result is practically cosmetic.

I wish to draw attention to the case of an Indian hanker who came to me at Amritsar in 1917. He had had an ordinary seventh-nerve paralysis, from which he had recovered a few months previously. The muscle balance of his mouth had gone wrong and was a usual in such cases. I gave him a showed him how to use it. After ck to me with the mouth pulled to the opposite side—that is to say, towards the nerve originally paralysed. The last I saw of him was two years afterwards. The shortening he had produced had remained permanent.

The muscle balance of the eye is exactly analogous to the muscle balance of the mouth. If we can alter the Indian hanker's mouth permanently by a course of electrical stimulation of the muscle on one side, we can similarly alter the muscle balance of the eye. There is no means of getting away from this issue.

While on a holiday with a friend recently in a village in Nova Scotia, a girl of 10 years of age was brought to me; she had 7½ degrees of external squint. I had no dark room nor apparatus with me. A local doctor kindly lent me an electro-magnetic apparatus. I spent a few sittings with the child, allowing her to play with the instrument so as to gain her confidence. I used an ordinary sewing needle as one pole, placing the other pole on the nape of the neck. With the eye cocaine I pushed the needle through the conjunctiva not more than one-eighth of an inch towards the affected muscle. She could not stand the hum of the instrument, so my friend did the make and break of the current with his hand. I gave her about fifty shocks of such strength as the child would put up with over the internal rectus of one eye in the morning, and over the internal rectus of the other eye in the evening. At the end of five days—ten sittings—the squint, as examined in open daylight, was reduced to 2 degrees.

I had then of necessity to leave this very interesting case, and the best I could do was to order her a pair of 1 D prisms. At this stage I secured a piece of red glass, and found that with it she had 7½ D, and without it had 2 D, showing that she was exercising 5½ fusion power.

It was noticeable in this child that the little shock produced caused the child to vomit occasionally after the sitting, and this tendency naturally limited the length of the sitting and the strength of the current used. This is not surprising, as in children or adults any shock associated with surgical interference with the eye often causes a vomiting of this kind. The right technique for this procedure has yet to be settled.

I would suggest that the patient should be put under gas for the minute or two required at each sitting, the eye being also cocaineized, a meridional slit made in the conjunctiva about one-eighth of an inch over the muscle, the pole insulated with sealing-wax to near the point, and the muscle submitted to a fairly strong current in this way twice a week.

If this is done I have no doubt the operator will get what shortening he requires with very few sittings; that he will be able to adjust the length of any extrinsic muscle of the eye to the physiological length; and that he will run no risk of mutilation. To emphasize the main issue of the procedure I advocate: If one can rapidly by means of a series of electric shocks shorten permanently and to any degree required the muscles which balance the mouth, by analogy you can similarly shorten permanently any of the extrinsic muscles which balance the eye. The procedure which I advocate would do away with all operations for muscle balance and with the use of prisms for this purpose.

PULSATILLA IN DYSMENORRHOEA.

BY

FREDERIC C. COLEY, M.D.,

PHYSICIAN TO THE NORTHERN COUNTIES HOSPITAL FOR DISEASES OF
THE CHEST; CONSULTING PHYSICIAN TO THE HOSPITAL FOR
CHILDREN, NEWCASTLE-UPON-TYNE.

TWENTY-ONE years ago a patient came to me suffering, amongst other things, from dysmenorrhoea. It was very severe, causing nausea and prostration, and the pain sometimes reduced her to helplessness. She was then over 30, and had suffered in this way since her third period, at the beginning of which she had "taken cold." I prescribed, by a fortunate inspiration, pulsatilla, a remedy which I had previously been led to regard as useless. The result was such that the patient afterwards told me that the fee she paid me was the best investment she had ever made in her life. Since then I must have used pulsatilla in hundreds of cases. In many it has been entirely successful. In most it has given great relief. I believe those in which it has completely failed have been few.

The cases in which I prescribe pulsatilla give a history of this kind: They have pain for the first day or two of each

catamenial period. Sometimes it begins a day or so before the period. The loss is usually small. I have not been accustomed to use it where the amount is excessive, lasting six days or more, and attended with passage of clots, pain continuing through the whole of the period, or nearly so. Most of the patients that I have treated have been unmarried. Married women having this type of dysmenorrhoea are apt to be sterile.

I do not pretend to know the precise pathology of these cases. I never make a vaginal examination in them, which is mischievous where it is not necessary. I am quite satisfied with the knowledge that in the great majority of patients giving the history above detailed pulsatilla affords wonderful relief. When I prescribe it I usually give the following explanation: "You may get great and immediate relief at the first trial of the medicine. That often happens. But do not be disappointed if it does not. If you get any relief at all at first, you may expect with great confidence that the benefit when you use it at the next period will be much greater. Probably when it has been used at five or six periods the pain will be entirely abolished, after which the medicine may be given up with very little fear of a relapse. But if that should occur at any time, the medicine may be resumed with good effect." The cases in which these prophecies have been unfulfilled have been in my experience very few. How pulsatilla relieves dysmenorrhoea I do not know. I have never known it to produce any undesirable effect, or indeed any other effect at all than that for which it was prescribed. It is certainly not a narcotic. The formula I use is:

R Tr pulsatilla 5iv
Spt. chlorof. 3ij
Aq chlorof. ad 3vj
Two teaspoonfuls of this to be taken as soon as menstrual (or pro-menstrual) pain begins, and every three hours while pain continues.

It cannot be supposed that the minute quantity of chloroform contained in 5ij of this mixture materially aids the pulsatilla. But it is most efficient as a preservative, so that I tell the patient that if the bottleful is not finished when pain ceases the rest of it may be kept for use at the next period.

It may be objected that suggestion is largely concerned in the success of this treatment. Absolutely to disprove this would be difficult. But the remarkable uniformity of the results makes it exceedingly improbable. To me it is a question of merely academic interest. What I care for is that severe pain, often producing serious disability, is relieved, and in many cases entirely abolished, by a remedy which is quite harmless and in no way disagreeable. And these are advantages which certainly cannot be claimed for the stem pessaries which were in vogue in my younger days, or the operations for dilatation of the cervix which I have seen described in recent works.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

OBSTRUCTION OF THE PELVIC COLON BY THE PEDICLE OF AN OVARIAN CYST.

The notes of the following case, in which the obstruction was caused in a remarkable manner, seem to merit publication.

On August 28th, 1921 I was called by a local Muslim doctor to see his mother-in-law, a lady of 55, who was obviously suffering from symptoms indicating an obstruction of the bowel, incomplete in character. On the previous day she had had a sudden attack of moderately severe pain in the lower abdomen, followed by vomiting (once). An enema given in the evening had resulted in the passage of a little faeces and flatus, but did not relieve the pain. When I saw her, her abdomen was slightly distended, particularly over the caecal and sigmoid areas; tenderness was not marked, and there was no rigidity. The pulse rate was 80, the temperature normal. She gave no history of genito-urinary trouble.

Castor oil was ordered, but was returned, and an enema with turpentine produced a small motion without passage of flatus. On the following day her condition was much the same, and she was removed to hospital for further observation, and in case the necessity for operation should arise. A further enema resulted in the passage of considerable flatus. During this and the following day her condition was chiefly remarkable for the variation in the severity of the local symptoms. Pulse and temperature remained unelevated. The spasms of pain varied in their intensity and duration, and frequent enemata only occasionally produced flatus. Abdominal distension was, on the whole, less marked. A small stool was passed on the 30th after an enema. On the 31st the pulse rose to 96 and the temperature to 99° F., and her general condition was obviously worse. She complained bitterly of the increase of pain after the enemata. I advised a laparotomy, but

first insisted on making a vaginal examination. This revealed an ill-defined lump on the right side. The fundus uteri could not be felt.

On opening the abdomen under spinal anaesthesia (stovaine) by a subumbilical incision, the omentum was seen passing down to become attached to a right-sided ovarian cyst about the size of a cricket ball. The uterus was displaced to the left and the pelvic colon was found to be ensnared by the cyst pedicle in a most remarkable manner. The pedicle, under considerable tension, about the thickness of the index finger, and showing several twists, passed from the uterus posterior to the obstructed loop, then over the latter from behind forwards, and finally to the left and posterior to its proximal portion, emerging under cover of this to reach the base of the cyst. The cyst was lying horizontally, with its apex to the right and pointing downwards slightly. The loop of colon was moderately distended, and showed a fairly pronounced ring at the point of constriction.

After ligaturing and dividing the partially adherent omentum, the obstruction was first relieved by division of the pedicle between ligatures at the point where it appeared from behind the loop and the cyst removed. The remaining (proximal) portion of pedicle was then ligatured and removed from its uterine attachment. The broad ligament on the side of the cyst was extremely rudimentary. The abdomen was closed in layers without drainage. Apart from a rise of temperature on the third and fourth days due to malaria, which promptly yielded to intramuscular injections of quinine, the patient made an uneventful recovery.

The cyst was incised after removal and proved to be a dermoid containing a large quantity of hair in about 12 ounces of viscid dark yellow fluid. The total length of the pedicle was about 8 inches; it was dark red in colour, due to extravasation of blood, and it presented an unusual feature in that its diameter was uniform throughout.

How the cyst and its pedicle came to establish the relations found at operation it is almost impossible to guess, but it seems reasonable to suppose that the omentum was to a large extent responsible for their maintenance. The adhesions were recent, and probably followed the twisting of the pedicle. This being abnormally long must, I think, be regarded as the primary factor in the causation of the obstruction, and no doubt the weight of the cyst, aided by gravity, prevented the bowel escaping from the noose.

I wish to thank the Director of Health Services in Iraq for permission to publish these notes.

G. S. WOODMAN, M.B., B.S. Dunelm., F.R.C.S. Edin.

Mosul.

ERUPTION RESEMBLING VARICELLA IN LOBAR PNEUMONIA.

As there has recently been correspondence relating to the possible identity of the virus of herpes with that of varicella it may be opportune to place on record a case of lobar pneumonia accompanied by herpes labialis, and, on the approach of crisis, also by an eruption clinically identical with or resembling very closely that of varicella.

A young man, aged 24, was admitted to the Mildmay Mission Hospital at Bethnal Green on August 1st, 1921, suffering from acute lobar pneumonia. There was a good deal of herpes around the nose and mouth. He stated that after feeling unwell for a few days he was taken suddenly ill three days before admission with pain in the chest and vomiting. He was found to have dullness at the base of the right lung, and a well marked patch of consolidation extending from the second to the sixth costal cartilage and three to four finger-widths from the right sternal border. Diminution of resonance extended considerably below this, but cleared up without further sign of effusion.

On August 4th there was an outbreak of red spots, quite irregularly distributed, on the upper part of the chest. These took five or six days to clear up, but only a very few of them showed vesicles. On August 6th there was an extensive vesicular outbreak on the back, covering the whole of it in an irregular manner and showing no tendency to group along the nerve tracks. The larger of these became pustular and terminated by scabbing. Umbilicated vesicles were not observed.

The whole eruption was not simultaneous in development, and it lasted many days; but I regret to say that the date of the termination of scabbing is not marked in my notes.

London, W.

WM. SALISBURY SHARPE, M.D., M.R.C.P.

THE OPERATION OF CHOLECYSTGASTROSTOMY.

To your issue of November 19th, 1921, Mr. C. A. Moore, of Bristol, contributed an interesting case of pancreatic tumour, and added a valuable review of the literature of cholecyst-gastrostomy. His remark that "cases in the literature since 1914 are naturally scarce" prompts me to add the following case of malignant disease of the pancreas to the list.

A railwayman, aged 45, was admitted to hospital in August, 1922, suffering from chronic obstructive jaundice of several months' duration. He complained of intermittent pain in the upper abdomen, and intolerable itching from jaundice, which was deep and progressive. In the preceding six months he had lost 14 lb. There was slight uniform distension of the abdomen, and a distended gall

bladder was easily palpable as a mobile globular tumour, situate midway between the umbilicus and the right costal margin. The stools were pale, bulky, and greasy. No trace of prostatic was present, but an abundance of undigested muscle fibre and an excess of mucus. Glycosuria was present, Loeffler's test was negative, and the excretion of diastase in the urine, normal in amount.

On account of the intolerable pruritus, the abdomen was opened and cholecystgastrostomy performed, after aspiration of the gall bladder. The head of the pancreas was found to be enlarged, nodular, stony hard, and overhanging the duodenum. The latter was deeply placed and firmly held by adhesions, rendering anastomosis of it with the stomach impossible without undue traction.

I feel diffidence in drawing inferences from a single experience of the operation, but I was impressed by the ease of its performance, the rapid disappearance of the jaundice with the attendant itching, and the remarkable tolerance of the stomach to the free drainage of bile into its lumen. At no time subsequent to operation was he troubled with nausea or vomiting. The patient lived six months in comparative comfort, despite the onset of hydropertoneum, which necessitated tapping on two occasions.

From the standpoint of technique, cholecystgastrostomy would seem to possess many advantages, as Mr. Moore points out.

The barium skiagrams were interesting, for in the most recent contribution¹ to the literature to which I have had access it is stated that "Roentgen-ray studies following cholecystgastrostomy have shown that bismuth and barium do not enter the gall bladder." In the case here reported the barium skiagram clearly showed the passage of a portion of the meal through the stoma into the gall bladder, and its accumulation in the latter viscus. In fact, the appearance depicted on the plates was not unlike that of an hour-glass stomach with two unequal pouches.

GERALD RALPHS,
Assistant Surgeon, Ashton-under-Lyne
Infirmary.

Dukinfield.

Reports of Societies.

PNEUMOPERITONEUM OF THE PELVIS IN GYNAECOLOGICAL DIAGNOSIS.

At a meeting of the Edinburgh Obstetrical Society held on December 14th, 1921, with the President, Dr. LAMOND LACKIE, in the chair, Dr. LANCE IMPEY read a paper on "Pneumoperitoneum of the pelvis as an aid to gynaecological diagnosis."

Dr. Impey said that for the past two years extensive work on pneumoperitoneum of the pelvis had been carried out at the Michigan University Hospital, Ann Arbor, by Peterson and Van Zwaluwenburg. No expensive or elaborate apparatus was necessary. The table was an ordinary operating table which could be lowered at one end. Carbon dioxide was used and was stored in a commercial cylinder, the flow of gas from the cylinder being controlled by a gas pressure valve. The quantity of gas injected was accurately measured by an inverted siphon pulsating meter, commonly used by engineers for the measurement of chlorine gas. A manometer indicated the pressure under which the gas passed into the patient. If the gas was injected through the uterus a metal cannula was passed into the cervix. The backward flow of gas was prevented by a rubber obturator, which fits into the external os. When the abdominal route was indicated, a lumbar puncture needle was used to perforate the abdominal wall. Numerous tests showed that the CO₂ in ordinary commercial cylinders contains no bacteria. Carbon dioxide was used in preference to oxygen, as it is absorbed in fifteen to thirty minutes. A portable x-ray apparatus was used and the photograph taken immediately after the inflation. Unless there were definite contra-indications, such as a recent inflammatory condition, or a pregnancy, the first attempt was made to pass the gas by the transuterine method. If the tubes were permeable the gas passed into the peritoneal cavity with the manometer showing a low pressure of 30 to 40, if there was resistance the pressure rose to 200. It was not advisable to allow the pressure to rise above 200. If the gas would not pass through the tubes it was injected through the abdominal wall. The point of election for the puncture, unless there were contra-indications such as adherent intestines, or a tumour, was two inches below the umbilicus in the mid line. The patient was next placed face down-

wards in the knee-chest position on the tilting table, an inclined board, with the upper border cut away to fit the pendulous abdomen, being used to support the thigh. The table was tilted forward to an angle of 20 degrees, and the x-ray photographs taken, stereograms being taken in all cases. The photographs showed very clearly all of the pelvic organs. The uterus was shown as two cross-sections—the one representing the body and the other the supracervical portion, or isthmus. The broad ligament, ovaries, and tubes were clearly seen. In some cases even the round ligaments could be made out. Fibroids of the uterus showed an irregular outline, and the mass had a greater density than normal. Ovarian cysts produced a picture that would rarely leave one in doubt. The most characteristic picture was of a bilateral salpingitis. In a number of cases pregnancy had been recognized as early as the sixth week. The signs consisted in the symmetrical enlargement laterally of the isthmus. This was probably due to the increase in the blood supply and to the early softening of the lower uterine segment. The uterus itself was also enlarged, but its density was less than normal, and the shadow was homogeneous and uniformly smoothly rounded.

Dr. Impey added that early cases of tuberculous salpingitis, when the tubes were soft and pliable and offered no resistance to the examining finger, had been discovered in x-ray photographs. A differential diagnosis between tumours arising from the pelvis or abdominal cavity was made easier by pneumoperitoneum. Though detailed notes had been kept in all cases, of which there had been over 300, there was no evidence of any harm being caused by the inflation.

In the discussion that followed, Dr. BARNARD doubted whether there was much real advantage in diagnosing pregnancy as early as the sixth week. Dr. BALLANTYNE thought that there might be danger of causing abortion or of causing peritonitis by driving infected matter from the tubes into the peritoneal cavity.

Mr. HARTLEY had seen the method used frequently in the Royal Infirmary in abdominal diagnosis. They had used oxygen, and there did not seem to be much discomfort to the patient. His opinion was that, while in certain cases it might be helpful, it would not revolutionize surgical diagnosis. Dr. H. S. DAVIDSON thought the method might be of service in cases of doubtful diagnosis, and especially in tuberculous conditions.

Dr. FORMYCE thought that patients in this country would not submit to the ordeal, but judging by the photographs shown the method might be of value when adhesions were present. He thought there might be a risk of driving pus from a tube into the peritoneal cavity, or of causing abortion. Dr. HUG FERGUSON was also of opinion that difficulty would be experienced in getting patients to submit to it, and that in most cases an expert bimanual examination would give all the necessary information.

Dr. R. W. JOHNSTON suggested the possibility of the patient being poisoned by absorption of carbon dioxide in the rapid disappearance of the gas from the peritoneal cavity. The President was interested to hear that among 300 cases there had not been a single accident, as he also had been struck by the possible danger of causing abortion, or of infecting the peritoneal cavity.

DISEASE AND REVERSION.

A MEETING of the Liverpool Medical Institution was held on December 22nd, with the vice-president, Dr. R. W. MACKENNA, in the chair, when Dr. MACALISTER read a paper on "Some relationships between disease and reversionary characteristics." He pointed out that man's present stage of development had probably been acquired owing to conditions of environment and opportunity by which his ancestors were surrounded. This had led to his having structural and physiological complexities presenting considerable variations, and sometimes involving deviation from perfection. His habits as to food had undergone most extraordinary changes, and it was probable that the conditions which had rendered him capable of metabolizing any type of food, whether animal or vegetable, must have resulted in great developmental changes. Dr. Macalister proceeded to speak of anatomical and physiological imperfections which in present reversion to types characteristic of some of those ancestors from which man was originally evolved, limiting his observations to the metabolic side of the question. He referred to variations, sometimes towards the carnivorous type

¹ Head: Cholecystgastrostomy. *Surgery, Gynecology, and Obstetrics* (abstract of Surgery), November, 1922.

of metabolism, sometimes towards the vegetarian type, and suggested that the stocks from which man originated when on the carnivorous side might be regarded as having a latent vegetarian metabolism, whereas on the vegetarian side it would be latent carnivorous one. This hypothesis would explain the possibility of there being an adaptability to new dietetic conditions in the early stages of evolution. He spoke of the important part played by the vestigial structures in the study of this subject, and pointed to the physiological idiosyncrasies, which were sometimes unusually well marked. He dwelt especially on the functional capacity of the organs of metabolism, and showed that whereas the majority of people were furnished with organs adequate in size for dealing with a variety of food, some were provided with too small a liver or pancreas, or kidneys which were unable to eliminate some specialized materials, or in which the general eliminative functions were apt to be slow. Those people probably represented variations to ancestral types of metabolism, and disease might be avoided by adherence to diets corresponding to the type to which they belonged. He referred particularly to polymastia, not only in its relation to multiparous births, but also to the fact that subjects of that vestigial condition also presented metabolic reversions. He indicated that if the personal idiosyncrasy was met there was no reason why these variants should be regarded as abnormal, or should suffer ill health if they could only be taught to diet themselves in accordance with their physiological requirements. Having spoken of the metabolic changes which were associated with the various climacteric periods of life, Dr. Macalister concluded by alluding to racial reversions, and by way of illustration gave examples of types where one child in a family presented pure Anglo-Saxon characteristics, whereas the other children had none. In three such cases it was interesting that the families had old Anglo-Saxon names, which had quite possibly descended through many generations.

Vaccine Therapy.

Dr. E. CRONIN LOWE read a paper upon the rationale of vaccine therapy, illustrated by several diagrammatic lantern slides showing primarily that in the maintenance of a natural unity in health, endocrine glandular functions as well as all hygienic conditions should be essentially considered as undertaking the vaccine treatment of any case. He held out that vaccine therapy was not an alternative mode of treatment but essentially an accessory one. Most of the slides dealt with details concerning the necessarily full elimination of any case before undertaking vaccine treatment. Ordinary detoxicated and sensitized vaccines were shown with and two diagrammatic charts shown, which were adapted to differentiate the comparative usefulness of these vaccine preparations for various conditions. A particular point was made of the need for attempting to assess the importance of bacterial findings in any case by means of the films obtainable from blood count pictures and other serological tests. Particular stress was laid upon the importance of serving focal reactions as an essential guide in vaccine treatment, particularly concerning dosage and the intervals between doses.

MEETING of the Aberdeen Medico-Chirurgical Society held on December 1st, 1921, with the President, Mr. JOTT RIDDELL, in the chair. Professor C. R. MARSHALL, in a address on the subject of "Convulsions," held that all convulsive movements, considered as involuntary contractions of volitional muscles of central origin, were of the order whether they were true tremors, as in paralysis agitans, or typical convulsive seizures as in epilepsy. Movements of cerebral origin were alone considered and the motor system was stated to possess no automatism. The causes of convulsions were briefly dealt with and the effects of a slowly growing cerebral convulsant poison, as an example of a widely diffuse stimulus, were described and illustrated. Lability of the muscles in chorea was regarded as an important factor in the production of the characteristic movements. The difficulty of explaining the commencement of epileptic attacks was referred to. Powerful psychical stimuli did not necessarily cause them, but Professor Marshall stated that these might possibly be initiated by psychical stimuli which were associated with altered vagotonus. In cerebral epilepsy such psychical stimuli might occur in fits. The subject matter of the address was discussed by members present.

On December 16th the annual dinner of the society was held in the society's rooms. The attendance numbered 68 persons and guests.

Reviews.

INDUSTRIAL FATIGUE AND EFFICIENCY.

THERE can be few English men or English women of adult age in 1914 and surviving the Armistice who have not amongst their most vivid memories what they did or suffered in the great war. Many war-time experiences were more dramatic, yet none, perhaps, were stranger than those of the little band recruited by the Health of Munition Workers Committee. Rich and poor, learned and unlearned, have fought side by side in many previous campaigns; this was the first to send academic physiologists and professors of philosophy into armament factories there to apply to industrial problems intellectual methods acquired for other purposes.

To the now scattered members of that regiment Dr. VERNON's book on *Industrial Fatigue and Efficiency*¹ will recall many strenuous hours, some failures, some successes; to a wider public it should demonstrate the enduring value of the scientific habit of mind. We do not wish to exaggerate the importance of the work done by Dr. Vernon and his colleagues; some of their results may be open to the criticism passed, we think by Mr. Bernard Shaw, on a result of Jevons—namely, that he proved by the help of the differential calculus what the working man had discovered without any calculus a generation earlier. Dr. Vernon, again, although a lucid is not exactly an exhilarating writer, and does not always resist the temptation to digress into speculative political economy with which he has no special concern. But when all discounts properly chargeable have been made, the difference between such a book as this and such works as—to cite one very famous example—Taylor's *Principles of Scientific Management*, is the difference between the product of a trained scientific intelligence and that of an acute but undisciplined mind.

Dr. Vernon in the first place describes how industrial output may be measured statistically, how it varies from hour to hour, from shift to shift, and from day to day. He shows the effects of changing the length of the working time and the arrangement of the shifts. He then illustrates the efficacy of rest periods and explains a statistical method of detecting deliberate limitation of output. In the next two chapters the etiology of "Lost Time," and the connexion between industrial employment and sickness or mortality are examined. Then the causation and prevention of industrial accidents are discussed, and the book concludes with a summary of work on general factory environmental conditions and a brief statement of practical inferences.

A large proportion of the volume is necessarily devoted to the exposition of results published in the reports and memoranda of the Health of Munition Workers Committee or of the Fatigue Research Board, upon which we commented at the time of first publication and need not therefore particularize. Amongst the most strikingly important general results are the evidence, amounting to demonstration, that "overtime" and Sunday work are always evils and that the optimum hours of labour cannot be the same for all branches of industry. Much eminently practical advice as to how output may be improved is given, and the quality of the scientifically trained mind is shown by the caution with which Dr. Vernon eschews promises that if such or such a plan be followed output will go up by leaps and bounds. His critical remarks on pp. 111-112 will probably be resented by those who speak of Taylor and Taylorism in the style of an enthusiastic advertiser, but seem to us very much to the point.

From the academic point of view, the value of the book would have been enhanced had the actual data been given more frequently, a remark which especially applies to the statistical study of limitation of output, since the goodness of fit of the curves there used cannot be tested on the basis of the information provided. Sometimes (for example, on p. 94) the statistical data seem hardly adequate to support inferences attempted to be drawn. But, taken as a whole, the book reaches a far higher standard than any work on a similar subject which we have seen before, and should be a source of inspiration to future investigators. Dr. Vernon is one of the most recent, and not one of the least successful,

¹*Industrial Fatigue and Efficiency*. By H. M. Vernon, M.A., M.D. London: J. Houlledge and Sons, Ltd. 1921. (Demy 8vo. pp. 272. 12s. 6d. net.)

examples of men who, having attained success in pure science, have earned still higher praise in applying scientific methods to the study of everyday life.

DIXON'S PHARMACOLOGY.

THE new edition of Dixon's *Pharmacology* is very welcome. It does not aim at being a manual of materia medica nor yet of therapeutics, and, as the author indicates, therapeutics are introduced chiefly in illustration of the pharmacological action of drugs. Due mention is made of drugs little used in therapeutics when their discussion serves to illustrate important group relationships, but they are not unduly laboured. The object of the author is to illustrate clearly the mode of action of the principal drugs and to emphasize the importance of accuracy of thought and the application of physiological methods and reasoning to their study. To this end the book is well illustrated with tracings and records of experiments.

Standardization, recent work on ergot and its constituents, on thyroid medication, on the cinchona alkaloids, and on organic arsenic preparations and the modern application of antimony, are all included, but under digitalis no mention is made of the case with which effects can rapidly be produced if sufficiently large doses of the drug be given. The anthelmintic action of thymol might have been given more prominence, for it is extensively used, especially in the tropics, in the treatment of ankylostomiasis. In the case of many drugs in common use the precise mode of action is still in doubt or not as yet readily demonstrable by animal experiment, hence in such a book as this there is almost necessarily a certain disproportion between the amount of space devoted to a group of drugs and their importance in practical therapeutics. This is doubtless the result of the regulations of universities and examining bodies which make pharmacology a subject of the second examination taken before clinical work has been commenced. It is greatly to be hoped that the student will carry with him to the wards the fruits of the author's teaching and have constantly in mind the analytical method of inquiry inculcated in this book.

The popularity which Professor Dixon's manual has enjoyed in the past will be enhanced by the thorough revision which it has undergone for the present edition.

MALARIA IN MALAYA.

DURING the present century a great deal of progress has been made in the prevention of malaria throughout the Federated Malay States, and in 1911 an account of what was being done was written by Dr. M. Watson of the Government Medical Service. His book has long been out of print, but has recently reached its second edition.² In this excellent and ably-written volume the reader will find how much can be done in the control of malaria by the method of anopheline reduction in rural areas.

The stock example of practical success attained by this method, the destruction of mosquitos, to put it roughly, is, of course, the Panama Canal zone; but for the prevention of malaria among the workers the canal could not have been made. In the Federated Malay States the problems of the antimalarial campaign are far more complicated, as Dr. Watson points out. Here the work has been done by Government in the ordinary course of its sanitary administration, and by the estates which are commercial undertakings; the area of operations extends over thousands of square miles, and not a mere fifty square miles as at Panama; and the population is under only a certain amount of discipline, the labour being free and not indentured. In Malaya many varieties of *Anopheles* are malaria carriers, each with its own special taste in habitat. Thus, in the non-malarial coastal mangrove zones when the forest is felled and the tide obstructed *A. balabacensis* may appear and make the area intensely malarial. The part of the mangrove zone covered only by the spring tides and the coastal plains are naturally malarial from the presence of *A. umbrosus*; both these anophelines are got rid of by clean weeded drains and good drainage. In the low coastal hills malaria persists after *A. umbrosus* has

been eliminated by drainage, because of the appearance of *A. maculatus*; this mosquito can be completely abolished from ravines by subsoil drainage or by spraying with oil. The inland plains, healthy when opened, may become malarial if the natural malaria carrier, *A. acutus*, appears; the inland hills, like the coastal hills, become intensely malarial when the ravines are opened, because *A. maculatus* then appears in them. Dr. Watson considers that in opening land in the inland hills malaria can in future be avoided by refraining from felling the jungle in the ravines.

Leaving the countryside and turning to the towns of Malaya, the history of the antimalarial campaigns in the town of Klang and in Port Swettenham is detailed by their originator, the author; and special chapters are given to the antimalarial work undertaken in various estates, in the swamps, in the plains, and in the hills. There are chapters also on the effects of malaria on Europeans and coolies, on the use of quinine, on the destruction of mosquito larvae by the use of mineral oil, on screening against mosquitos, and on other subjects of great interest to all dwellers in malarial countries. Dr. A. R. Wellington contributes an account of the successful antimalarial campaign in the town of Kuala Lumpur, and Dr. P. S. Hunter a chapter on the antimalarial work carried out at Singapore.

The economic importance of the prevention of malaria in countries like the Federated Malay States can hardly be over-estimated, and Dr. Watson's volume gives a singularly clear and complete account of the methods found successful in bringing about this most desirable result. The book is well got up, and contains over a hundred first-rate photographic illustrations. It should be in the hands of all medical men, whether in the public services or no, whose work lies in malarial areas.

SURGERY OF THE STOMACH AND DUODENUM.

MR. JAMES SHERREN has published in the form of a slim book a short series of lectures on *The Surgery of the Stomach and Duodenum*.¹ The little volume is a valuable addition to medical literature. Its chief claim to consideration is the fact that it is an absolutely personal record, based on the author's wide experience. Here will be found no shewcases of symptoms and signs gleaned from other people's fields. The facts set down are those which Mr. Sherren has himself observed. Naturally a certain dogmatism pervades the writing, but since the lectures are presumably intended for students, this is an advantage. Students, both qualified and unqualified, will derive great pleasure and great gain from reading the book.

It opens with a short chapter on the etiology and pathology of gastric and duodenal ulcer, brief mention being made of the more important experimental work. Mr. Sherren comes down heavily on the side of those who believe infection to be the chief cause of ulceration, stasis and hyperacidity being added factors. Histories are given of several interesting cases illustrating the dependence of ulcer on inflammation elsewhere within the abdomen. The symptoms of acute and chronic gastric ulcer follow. There are some interesting remarks on the uselessness of gastro-enterostomy in bleeding from acute ulcers and on gastrostaxis.

In chronic ulcer Mr. Sherren lays down some very sound rules as to diagnosis, without troubling greatly to differentiate clear cut symptom complexes according to the precise site of the lesion. For students this is a wise course; conditions in which questions arise are partly covered during the discussion of hour-glass stomach and pyloric stenosis. But it would be interesting to know what the author really thinks. The reader is left similarly unsatisfied in many places and we can only hope that some day a larger book may be forthcoming on the lines of the present. Two or three good cases are recorded illustrating the difficulty of distinguishing a duodenal ulcer from gall stones and even from renal calculus in certain circumstances.

Mr. Sherren proposes that gastro-enterostomy should be performed three months after perforation of a duodenal ulcer, if it has been deemed unwise to proceed with the short circuit at the primary operation.

Two chapters on carcinoma of the stomach close the book. Mr. Sherren is, of course, a firm believer in the existence of a close relation between chronic gastric ulcer and malignant growth. Reference is made to records of the Mayo clinic, which, as is well known, give an exceedingly high cancer

¹ *A Manual of Pharmacology*. By W. E. Dixon, M.A., M.D., B.S., R.S.C., D.P.H., F.R.S. Fifth edition, completely revised. London: Edward Arnold, 1921. (Demy 8vo, pp. 483; 92 figures. 18s. net.)

² *The Prevention of Malaria in the Federated Malay States*. By M. Watson, M.D., with contributions by P. S. Hunter, M.A., M.B., and A. R. Wellington, M.R.C.S., L.D.S.P., and a preface by Sir R. Ross, K.C.B., M.D., F.R.S. Second edition, revised and enlarged. London: J. Murray, 1921. (Med. 8vo, pp. xxvii + 381; 115 figures. 35s. net.)

³ *Lectures on the Surgery of the Stomach and Duodenum*. By James Sherren, C.B.E., F.R.C.S. London: H. K. Lewis, 1921. (Cr. 8vo, pp. 324s. 6d. net.)

incidence in cases of chronic ulcer. The Rochester evidence is largely histological and is the expression of an opinion; it is not necessarily the expression of a universal truth. Of 165 ulcers removed as simple by Mr. Sherren there were definite evidences of malignancy in eleven. This corresponds more nearly with Moynihan's 10 per cent. than with the Mayo figures. There can, however, be little doubt that earlier and more efficient treatment of gastric ulcer would reduce largely the death roll from cancer of the stomach.

The book is a sober, well-reasoned summary of facts observed in an intensive experience of gastric and duodenal disease, and the story is told with a remarkable economy of words.

RADIO-DIAGNOSIS IN PULMONARY TUBERCULOSIS.

Le Radiodiagnostic dans la Tuberculose Pleuro-Pulmonaire, by Dr. ABREU, fills what has been a gap in French medical literature. After a short introduction by Dr. Rist, who collaborated in the work from the clinical side, there is an excellent explanation of the exact technique required to ensure the best results, both radiographic and radioscopy, definite rules of procedure being laid down for both. Considerable stress is laid on the necessity of always working at a definite distance from anticathode to plate (or screen); this distance, it is maintained, should be at least 32 inches. A further desideratum, especially in cases of phthisis, is that plates should be taken every 5, 10, 20, or 30 days in order to see whether a lesion is undergoing any changes; by doing this, old cured lesions can be distinguished from active disease. An important point is made for the accurate measurement of the various x-ray densities of the different thoracic shadows. The chapter which deals with this part of the subject is full of interest. It is pointed out that expressions such as "loss of transparency," "half opaque shadow," "complete opacity," etc., are entirely unscientific and may be misleading. The suggestion is that shadows on the x-ray plate should be definitely compared with the shadows cast by so many—one, two, three, or more—centimetres of water; and the normal opacities of the clavicles, the heart, the ribs, the liver, and so on, are put down in terms of centimetres of water. Without accepting all that the author endeavours to substantiate there can be no doubt that this method is one worthy of consideration.

Following upon this introductory portion of the book comes the main part, which deals with the x-ray changes seen in tubercle affecting the lungs and pleura. This part is profusely illustrated by radiographs of chest conditions, which are reproduced by a special process and printed on fine paper. There are sixteen of these, and each one illustrates a special feature or features of disease. These, and the other thirty-one figures, are very much better than those usually seen in French books on x-ray work. On the page opposite to each radiograph is set out a detailed description of the radiograph and what it shows, whilst the reasons for the diagnosis which follows are given. The work concludes with a short chapter in which the author discusses the real value of radiographic examination, and points out the many ways in which such an examination is not only of use but may be essential for the proper treatment of the case.

The writing is clear, lucid, and concise, and any one who possesses only a rudimentary knowledge of the French language should be able to understand it. We consider that this is a book which should be read by every radiologist, but it is not only the expert in this subject who will find it of use. The general practitioner, as well as the consulting physician, will find valuable information as to the possibilities of an x-ray examination of the chest in tubercle and the help that such an examination may afford, not only as regards actual diagnosis, but also in the study of the progress of the disease in any individual case.

CLINICAL DIAGNOSIS.

The fifth edition of *Clinical Diagnosis*,⁶ by Dr. C. P. EMERSON, Professor of Medicine in the Indiana University School of Medicine, is an excellent work for students and practitioners of medicine who want an account of the methods whereby

⁵ *Radiodiagnostic dans la Tuberculose Pleuro-Pulmonaire*. Par Dr. Manuel de Abreu. Préface du Dr. E. Rist. Paris: Masson et Cie. 1921. (Post 8vo, pp. 168; 16 plates, 31 figures. Fr. 15 net.)
⁶ *Clinical Diagnosis*. A Text book of Clinical Microscopy and Clinical Chemistry for Medical Students, Laboratory Workers, and Practitioners of Medicine. By C. P. Emerson, A.B., M.D. Fifth edition, entirely rewritten and reset. London: W. Heinemann (Medical Books), Ltd. 1921. (Med. 8vo, pp. xxx + 726; 5 plates, 151 figures. 35s. net.)

the pathological laboratory turns out its results. Its seven chapters describe in detail the chemical and microscopical methods of investigating the sputum, the urine, the contents of the stomach and of the intestine, the blood, the cerebro-spinal fluid, and various other pathological fluids. Those described are such as have been tested and approved by experience; the author shows much sound sense in his estimates of the value to be given to the several pieces of evidence brought out by these methods, and in his general interpretation of the laboratory findings.

Professor Emerson's style is clear and simple, and he writes with the authority conferred by wide experience. The book is well turned out; the illustrations are admirable and refreshingly free from the clichés with which so many of the books dealing with clinical diagnosis have made us familiar. We can strongly recommend Professor Emerson's volume to medical men and medical students in search of a trustworthy and complete textbook on the subject with which it deals.

NOTES ON BOOKS.

It is difficult to add anything about the second edition of Mr. WIDDOWSON'S *Notes on Dental Surgery and Pathology*,⁷ to what was said when the first edition was noticed in 1915. The dual objective of the book, which is intended to serve as a notebook for students and as a ready work of reference for practitioners, is perhaps hardly to be attained. The author endeavours to codify accepted signs and symptoms and the treatment and sequelae of dental disease. The result sometimes verges on the absurd; for instance, are we seriously to believe that all patients suffering from general debility and nervous irritation must before extraction be prepared by a tonic, or that a general anaesthetic is an absolute necessity before extraction? Again, many pages on which difficulties, complications, accidents, and sequelae of tooth extraction are enumerated might make the unwary think that it was one of the most serious operations in surgery. In the section on the treatment of fractures of the jaw, where it is directed that the mouth must be kept clean, we come across the statement that some advise rectal feeding owing to the great difficulty of attaining cleanliness of the mouth. Fuller details as to what local treatment might be of use would have been more helpful. In this edition illustrations showing the commoner forms of root canals are given; they are conventional, and only a small percentage of root canals actually approach the simplicity of formation shown. As we observed when reviewing the earlier edition, faults of this kind spoil the author's excellent intentions.

Dr. EMERY'S *Clinical Bacteriology and Haematology for Practitioners*⁸ is a book of established position, well known in pathological laboratories for its merits of conciseness and accuracy. The sixth edition now before us closely resembles the fifth; beginning with an account of the apparatus and technical processes recommended, it next gives a hundred pages to the diagnosis of about twenty infectious diseases. Then follows a section on the collection and examination of a number of morbid materials—pus, urine, exudates, and the like, with directions for the culture of bacteria and the preparation of sections. The last seventy pages are given to haematology and cyto-diagnosis. The plates and cuts with which the book is illustrated serve their purpose well; it may be noted that the word "streptothricosis" on pages ix, 77, and 309, should be "streptotrichosis." The book is to be warmly recommended to the attention of pathologists and of medical practitioners who like to do some of their own laboratory work.

The *Manuel de Coprologie Clinique*,⁹ by M. GOIFFON, sets out the ways in which laboratory examination of the stools may be of assistance in the diagnosis and treatment of intestinal diseases and disorders. It begins with a brief account of the physiology of digestion. The second part of the book, occupying over 140 pages, describes in detail the methods—microscopical, chemical and bacteriological—used in examining the stools. The third part describes the various characters of the motions in diseases of the different digestive organs and glands; the fourth part gives the therapeutic indications and suggestions to be derived from the results of the examination mentioned above. The book is clearly and temperately written; it should be of considerable service in the clinical laboratory.

⁷ *Notes on Dental Surgery and Pathology*. By T. W. Widdowson, L.D.S., R.C.S. Second edition. London: J. Paley Foss, and Danielsson, Ltd. 1921. (Fcap. 4to, pp. 285; 151 figures. 21s. net.)
⁸ *Clinical Bacteriology and Haematology for Practitioners*. By W. D'Este Emery, M.D., R.Sc.Lond. Sixth edition. London: J. K. Lewis and Co., Ltd. 1921. (Demy 8vo, pp. 324; 54 figures, 11 plates. 15s. net.)
⁹ *Manuel de Coprologie Clinique*. Par M. Goiffon. Préface de J. Ch. Roux. Paris: Masson et Cie. 1921. (Cr. 8vo, pp. 240; 16 figures, 2 plates. Fr. 12 net.)

There are persons admitting to late middle age and called by their friends old who, though they have heard much about the sun myth and have been chastened by Sir J. G. Frazer, yet like a fairy story for its own sake: to such we may commend *The Disobedient Kids*,¹³ a copy of which reached us only a day or two before Christmas. It is an unusual production, having been turned into English. Illustrated, and printed in Prague: it contains ten stories chosen from among those written over half a century ago by a Czech-Slovakian lady, Božena Němcová. The translation is by Dr. Tolman, at whose request the book has been sent to us. In the circumstances we cannot be sure how far the stories are indigenous; we find a 'Tom Thumb' story, and a repetition story of the style of the House that Jack Built, and others which may be either parallels or reminiscences. The volume is illustrated with much skill and humour by Artus Scheiner, whose drawings in colour and in black and white have been most excellently reproduced under the direction of the publisher. The English is good and clear, but some of the turns of expression have a transatlantic character. It is termed "literary," but we do not take the antithesis; is it colloquial or commercial?

Earlier numbers of the *Practical Handbook of British Birds*,¹⁴ which is being issued in serial form under the editorship of Mr. H. F. WITHERBY, have been noticed in this column. During the past year two more parts, the tenth and eleventh, have appeared: these include pages 81 to 256 and Plates 2 to 5 of Vol. II. Part X is devoted to birds of prey—owls, falcons, eagles, hawks, harriers, kites, kestrels, and their brethren; Part XI covers storks, herons, ibises and spoonbills, and a number of swans and geese. The standard of the letterpress and illustrations is well maintained. One of the six contributors to this excellent handbook—and the writer of all the notes on migration of birds—is Mr. N. F. Ticehurst, F.R.C.S., of St. Leonard's, who is a representative of medicine in the select company of scientific British ornithologists which includes (to name but two others) Dr. A. F. R. Wollaston and Dr. Philip Gosse.

The first part of Professor HERING's book on pathological physiology¹⁵ deals with the functional disorders of the heart, the vessels, and the blood, each described under two headings; the causes (or coefficients) giving rise to the disorder are first explained, and then the results to which these causes give rise. The book is clearly written, but gives no details of the experimental work or the literature upon which it is based. It is intended primarily for the use of medical students and their teachers, but also for medical men.

The Handbuch der Cystoskopie,¹⁶ by Professor Dr. LEOPOLD CASPER, is one of the most complete works on the theory and practice of cystoscopy that we have come across. The earlier chapters deal with the history and the construction of the modern cystoscope. The optics and mathematics of the subject are fully dealt with and provide somewhat stiff reading for those not especially interested in this somewhat technical side of cystoscopy. After describing the anatomy and appearance of the normal bladder the author considers the commoner pathological conditions encountered by the cystoscopist. These are illustrated both by means of black and white and of coloured plates, which are collected into an atlas at the end of the book. Some of these illustrations are unconvincing, and few of them can be considered first class. The work concludes with a chapter on cystography, photography of the bladder, and The work is one that will appeal to ex medical practitioners in general.

We have received an interleaved copy of the *Pharmacopœia of St. Bartholomew's Hospital*,¹⁷ in which the doses are given in both imperial and metric measures, as in the *British Pharmacopœia* of 1914. A few pages are devoted to the treatment of cases of poisoning, and a posological table is included. The book is of convenient size, and contains much additional information of service to those for whose use it is designed.

MEDICINAL AND DIETETIC PREPARATIONS.

Inoculation Tests for Protein Therapy.

BLACKLEY may be regarded as the discoverer of specific skin reactions in diseases due to hypersensitiveness to proteins, for in 1873 he showed that pollen rubbed into the scarified skin produced large urticarial wheals in patients suffering from hay fever. The observations of Pirquet and Schick upon the local reactions in serum disease, and the work of Arthus upon the local reactions in anaphylaxis, showed that in hypersensitive individuals and animals the injection of the specific protein to which they were hypersensitive produced a strong local reaction.

Auer and Lewis in 1910 pointed out that spasm of the bronchial muscles was characteristic of the anaphylactic reaction in guinea-pigs, and thus drew attention to the probability that asthma in man was due to hypersensitiveness to specific proteins. The fact that asthma is very frequently due to hypersensitiveness to proteins has since been established by numerous workers. Asthma may be caused by a very large number of different proteins of animal or vegetable origin, and the only way to ascertain the protein responsible is to test the sensitiveness of the patient's skin with a variety of pure proteins. The technique of determining, by means of skin reactions, the protein responsible for producing asthma was worked out by Walker and Wodehouse in 1916 and 1917. The method is now coming into general use and the technique is very simple: a light scratch, insufficient to draw blood, is made in the skin, and a dilute solution of protein is applied; if the patient is not sensitive there is no reaction, but if the patient is hypersensitive to the particular protein applied an urticarial wheal appears in from fifteen to thirty minutes. The severity of the reaction varies, a mild reaction consists in a wheal about one-quarter of an inch in diameter; in a severe reaction the wheal may be an inch in diameter and surrounded by an erythematous ring. The only hindrance in applying the test is the difficulty of obtaining a supply of purified sterile proteins.

Messrs. Duncan, Flockhart, and Co. of Edinburgh (104, Holyrood Road), have prepared pure protein solutions in a very convenient form; the solutions are in glass capillary tubes; they supply thirty-two different kinds of proteins, which are obtained from all the commonest animal and vegetable foods, and from substances, such as horse dandruff and pollen, which may be inhaled as dust. This outfit makes the testing of specific hypersensitiveness a very simple matter, for a dozen different proteins can easily be tested in less than an hour. Selections of dried proteins for these reactions have been available for some time, but the supply of the proteins in a soluble form ready for immediate use is obviously a great convenience, as it saves the trouble of preparing a large number of solutions. The exact clinical value of these tests is not yet fully known. About 50 per cent. of asthmatics show definite dermal hypersensitiveness to proteins, but unfortunately a large number of cases show dermal hypersensitiveness to several proteins. In these cases of multiple dermal hypersensitiveness the asthma usually is due only to one particular protein. A considerable number of normal persons, moreover, show dermal hypersensitiveness. A positive reaction with a particular protein in a case suffering from symptoms resembling asthma, therefore, does not prove conclusively either that the patient is an asthmatic, or that, even if he has asthma, the disease is due to the protein to which he has reacted. If due regard is paid to the clinical history, the tests are, however, of great value in determining the cause of asthma. The advantage of knowing the cause of asthma is obvious, for it enables the patient to avoid the exciting cause, and also in many cases the patient can be desensitized by vaccine treatment.

Digifoline.

"Digifoline" is claimed to be a standard, constant, and permanent liquid preparation of digitalis suitable for internal, hypodermic, and intravenous use. It is a clear, light-coloured fluid, which does not produce any marked local reaction when injected hypodermically, and which, when tested on the frog, we find to have an activity equal to that of standardized tincture of digitalis. The manufacturers claim that digifolin (this spelling is, we think, to be preferred) is free from the irritant saponins which occur in the tincture. It contains all the active glucosides of digitalis, and is suitable for attending the administration of all doses are well known; to be produced by oral

¹³ The agents in London are Philip Allan and Co., and the price 6s. In America the agents are Harper Bros., New York, and the price 1 dollar. There seems to be a preference against this country, which is not explained.

¹⁴ London: Witherby and Co. 1921. 4s. 6d. net per part.

¹⁵ *Pathologische Physiologie. I. Abteilung: Die Funktionsstörungen des Herzens, des Gefässes und des Blutes.* By Dr. H. F. Hering. Leipzig: G. Thieme. 1921. (Med 8vo, pp. viii+120. M. 39.)

¹⁶ *Handbuch der Cystoskopie.* Von Dr. L. Casper. 4 Auflage. Leipzig: G. Thieme. 1921. (un. roy. 8vo, pp. 336; 161 figures, 12 plates. Bound. M. 24.)

¹⁷ *Pharmacopœia of St. Bartholomew's Hospital.* Edited by J. Langford Moore, F.C.S., Pharmacist to the Hospital. London: Spottiswoode, Ballantyne and Co., Ltd. 1921. (3½ x 5½, pp. 100.)

administration, and no preparation of digitalis has hitherto been prepared which is satisfactory for hypodermic or intravenous administration. Satisfactory therapeutic results have been reported to follow oral and hypodermic administration of digifolin, and the preparation appears to represent a distinct advance in digitalis preparations. Its exact value can only be known after more prolonged therapeutic trials have been made, but it seems to deserve a full trial. Digifolin is supplied in tablet and fluid form for oral administration, and in ampoules for hypodermic injection, by the Clayton Auline Company, 68½, Upper Thames Street, London, E.C.4.

THE VITAMIN THEORY IN RICKETS.

THE Report of the Medical Research Committee on Accessory Food Factors (Vitamins),¹ published in 1919, included a section dealing with rickets, which definitely placed it among the deficiency diseases. This conclusion was largely based upon the experimental work of E. Mellanby upon puppies, and stated that the cause of rickets in dogs was the lack in their food of an antirachitic factor, which had "in many respects a similar distribution to the fat-soluble A factor, and is possibly identical with that substance."

Dr. Mellanby himself in several later articles further expounded this new and interesting doctrine of rickets. It soon aroused wide interest, drew upon itself active discussion and criticism, and stimulated experimental study of the subject along these new lines he had laid down. Meanwhile he has been actively prosecuting his experiments, and he now sums up the results of five years' research in an interim report on "Experimental Rickets," just published.²

The broad statement may be fairly made that Dr. Mellanby takes now a larger view of the etiology of rickets than he did in the first account of his research. He does not put rickets in the same category of deficiency diseases as scurvy and beri-beri, where the withdrawal of one single element in diet, and that a factor unconnected with the provision of energy, is the decisive cause of the disease. He now admits the co-operation in rickets of other prejudicial factors—a disturbed balance of the main constituents of the diet, an unwholesome environment, lack of exercise. Beri-beri and scurvy are "nutritional diseases very limited in their etiology, but this does not hold in rickets" (p. 6).

Dr. Mellanby's Results.

Throughout the investigation the important criterion of rickets in the young dog was disturbed calcification in the growing bones, these changes being established by radiograms, by chemical analysis, and by histological evidence. The histological examination was the decisive one, and the crucial test was the presence of osteoid tissue.

It is clear that the diagnosis of rickets in these experiments has been made with scrupulous and strict accuracy; and the report is enriched by a beautiful series of radiograms and microscopic photographs of the bones. The conditions which produce the bony changes characteristic of rickets are given in the following order: "A deficiency of calcium and phosphorus in diet; a deficiency of fat containing the antirachitic vitamin in diet; excess of bread, other cereals and carbohydrates; absence of meat; excess of the protein moiety of caseinogen free from calcium; confinement." He goes on to say: "Because of the interdependence of all these dietetic factors, it is impossible to say what is the absolute amount of each necessary to produce the optimum result." But he adds: "Probably the most common cause of rickets in children is a combination of relatively deficient antirachitic vitamin and excessive bread" (p. 75). It will be readily seen that these conclusions are much more cautious and ambiguous than the original statement in the report concerning accessory food factors, "there is good evidence that rickets is a deficiency disease . . ." (p. 91).

Dr. Mellanby found that the diet most favourable to the rapid production of rickets in a young puppy was one containing an adequate amount of protein (separated milk), an excess of carbohydrate (bread), a sufficiency of water-soluble B and C vitamins and of salt, but very defective in fat. By adding measured amounts of various animal and vegetable fats and by observing the degree of rickets produced, he was able to estimate the antirachitic power of each variety of fat. The broad result was that animal fats were powerfully antirachitic; the vegetable oils were either feebly so, or destitute of this power. Now experiments on young rats showed that the animal and vegetable fats fell into the same groups in

respect of their power to promote growth, or according to the vitamin hypothesis in their content of fat-soluble A. There are discrepancies in this general statement; but on the whole it is true, and it led Mellanby to the conclusion that the disease in each species, lack of growth in the rat, and rickets in the puppy, is probably due to the same vitamin fat-soluble A. He finds other points in favour of this identity, in the fact that in each animal the disease took several weeks to develop, and also that beyond a certain age in the young rat and in the puppy, the respective diseased condition became very difficult to produce. These were the points in favour of rickets as a vitamin-deficiency disease, and of the identity of that vitamin with fat-soluble A shown to be essential for growth in rats.

But there are difficulties and objections to this interpretation. (1) In the first place, the puppies with rickets did not cease to grow; on the contrary, the worst degrees of rickets were found in those with most rapid growth, while if growth ceased, the rickety changes in bone were not produced. That is to say, we are asked to believe that this same vitamin stops growth in the young rat, while in the puppy it causes rickets but allows growth to proceed. (2) Then lean meat, a food poor in fat-soluble A for rats, was shown to possess definite antirachitic power in puppies. Several explanations of this difficulty are suggested, but they are conjectural and unsupported by evidence, and the discrepancy remains. (3) Green leaves are substances specially rich in fat-soluble A as shown by experiments on rats. In puppies a few experiments were made with cabbage and extracts of cabbage, and these failed to prevent rickets and set up diarrhoea. Further experiments in this direction are promised, and the importance of their success or failure is admitted.

Each of these difficulties is by itself not of small account; together they create a formidable obstacle to the acceptance of fat-soluble A as an antirachitic vitamin.

The report contains also interesting observations on other factors of diet and environment that favour the production of rickets. An excess of carbohydrate has an important effect in doing so; so has confinement; so also a defect of the caseinogen moiety of milk containing calcium. But these conditions only act when the diet is also defective in fatty substances rich in fat-soluble A. These observations are interesting both scientifically and clinically, but they need not be discussed in connexion with the present question of the vitamin theory in rickets. By increasing the complexity and number of agencies that produce rickets they certainly do not strengthen the vitamin theory, but, on the other hand, they do not seem to directly oppose it.

Other Investigations.

Now let us examine the results of other investigations carried out to test the doctrine of rickets as a deficiency disease produced by a defect of a vitamin similar to or identical with fat-soluble A. Noël Paton, Findlay, and Watson³ are strongly opposed to the vitamin theory in rickets. Taking pups from the same litter they produced rickets in some of these, confined in the laboratory but on a liberal diet of porridge and full-cream milk; while in others, at liberty in the country but fed on skimmed milk and porridge, no rickets developed. And in their last series of experiments by paying strict attention to cleanliness they have reared pups free from rickets on a series of diets with a low fat intake (even as low as 0.5 gram of milk fat per kilo of body weight), always provided that the total energy value of the diet was sufficient. They thus claim to have produced rickets in pups on a diet rich in fat-soluble A (an abundant supply of full-cream milk); and to have reared pups free from rickets on a diet very poor in fat-soluble A (separated milk and bread). From experimental and clinical evidence they propound the view that the primary factor in rickets is not dietetic but is the result of overcrowding and insanitary conditions, and that some kind of non-specific bacterial infection may be an important factor.

While in Britain most of the recent experimental work on rickets has been carried out on the dog, in America the cat has been chiefly used. In the last few months Hess, McCann and Pappenheimer, and Shipley, McCollum and co-workers have published interesting experimental work on rickets in the rat. This work is the more important in that the rat is the animal on which the work upon fat-soluble A has been done, and from which our knowledge of this accessory food factor has been derived. Hess's research⁴ dealt with a large series of young rats fed on a diet which was complete except

for a lack of fat-soluble A. The rats all failed to grow, and most developed a varying degree of keratitis, thus presenting the typical features of this deficiency disease. But none of the animals showed clinical evidence of rickets; and this test was strictly verified in 22 cases where microscopic examination of the bones failed to show the bony changes of rickets. Hess therefore concludes against the operation of fat-soluble A as a factor in rickets; and finds in these experiments a confirmation of his clinical experience that bad rickets in children is met with in almost every diet and independent of its high or low content of fat-soluble A.

Shipley and McCollum's work² also bears directly on the subject. Using, like the other American investigators, a synthetic diet, with all its constituents, organic and inorganic, exactly measured, they fed young rats with two diets, one defective in both fat-soluble A and phosphorus, the other defective alone in fat-soluble A. With each of these diets there were arrest of growth and keratitis, but in a number of animals on the first diet (not in all) the bones showed changes having a fundamental resemblance to, though not identical with, human rickets; while on the second diet, which included adequate phosphorus but defective fat-soluble A, no bony changes resembling rickets were produced. These experiments are interesting. In the first place, they show that rickets in the rat can be produced, though with difficulty, even if the animal has ceased to grow, but that the bony changes are not completely typical. Secondly, that a deficiency of fat-soluble A alone, the diet being otherwise complete, does not produce rickets. Thirdly, that lack of phosphorus, as of calcium, may be an important factor in the production of rickets; and in this connexion the authors quote an unpublished observation of Howland and Kramer, that in rickety children the phosphorus in the blood plasma is low, and that the administration of cod-liver oil, though itself lacking in phosphorus, increases the phosphorus in the blood. Shipley and McCollum, however, do not exclude fat-soluble A as a factor in rickets; it cannot be the sole factor, but it may influence it indirectly by its effect upon the metabolism of calcium and phosphorus.

A Summing Up.

In attempting to bring together and sum up this diversity of views upon the causation of rickets it will be easier to start from ground common to Mellanby and his critics. Mellanby himself no longer maintains the doctrine of rickets as a deficiency disease in the strict sense of that term as applied to beri-beri and scurvy. In his present interim report he gives the antirachitic vitamin ("probably identical with fat-soluble A") an important place among a number of other factors, dietetic and environmental. His experimental work has led him to the belief that, without a certain defect of fat-soluble A, rickets cannot be produced in the young dog, but that it is common for other factors to co-operate, though in varying degree. As stated already, his view is that the commonest cause of human rickets is a defect of the antirachitic factor, combined with an excess of bread. The experimental evidence that he and other workers have collected is very strongly in favour of a defect of certain fatty substances being the most important agent in the production of rickets in animals. That position seems definitely established by experiment, and also supported by clinical experience. But the crucial question is: Does the influence of these fats depend upon their content of fat-soluble A, or upon some other property or influence of cod-liver oil or milk fat? Let us take cod-liver oil, the most potent agent in the prevention and cure of rickets. What is the mechanism of its action: is it by virtue of its content in fat-soluble A, or is it by some obscure effect upon general metabolism and in particular upon the calcium metabolism of growing bones; is it the effect of its vitamin, or something else?

In the first place, let the facts against the vitamin theory be stated. (1) A diet defective only in fat-soluble A does not produce rickets in rats, but simply arrest of growth and osteoporosis (Shipley and McCollum, and Hess.) Rickets is a disease of growth, and develops rarely and with difficulty when growth is arrested. (2) A substance rich in fat-soluble A—cabbage leaves—has failed to prevent rickets in puppies. (3) A substance poor in fat-soluble A—lean meat-fibre—has a definite antirachitic action in puppies. (4) Where the diet is adequate in fat-soluble A—10 grams of milk-fat per kilo—rickets has been produced in puppies confined in unwholesome conditions (Noël Paton, Findlay, and Watson). (5) Well attested cases of rickets in children on an abundant milk diet are reported (Hess and Unger and others).

In favour of the vitamin theory, Mellanby brings three considerations: (1) There is general correspondence of certain fats and oils in their antirachitic power with their potency as sources of fat-soluble A. (2) Rickets in the dog, like arrest of growth in the rat, takes a number of weeks to develop. (3) Both are diseases of young animals, and can only be produced with difficulty after a certain age.

Though further research may redress the balance, in the meantime the weight of the evidence, experimental and clinical, seems to be against the view that the specific action of certain fats and oils in rickets is due to their associated vitamin, fat-soluble A. Another explanation of their undoubted pre-eminence in the prevention and cure of rickets is that in some way these food substances influence general metabolism, and especially the deposit of calcium in growing bone; and that their withdrawal from the diet deranges that metabolism. They are certainly the most powerful single agents in promoting calcium metabolism.

But other factors of diet and environment also have their influence in the same mechanism. It does not seem possible to reject the evidence, experimental and clinical, that genuine rickets may be produced where the diet is adequate both in the balance of its food elements and in its content of vitamin, but where the young and growing child or animal is kept in an insanitary and sunless environment. Such cases seem to contradict the vitamin theory of rickets, and to be only explained by some wider explanation of its causation.

THE TEACHING OF MEDICINE AND SURGERY.

NEW PLANS OF THE LEEDS MEDICAL SCHOOL.

(From our Correspondent.)

THE well known and much discussed report of Sir George Newman on the subject of medical education has been under the careful consideration of those concerned in Leeds since it was issued. From the first the desirability of securing the services of whole-time professors was called in question, if the object of this was to form units which should be responsible for the education of the general body of the students of a school. It was also deemed unlikely that any physician or surgeon of established reputation as a teacher would consent to devote himself entirely to hospital work to the complete exclusion of private consulting practice, even for a much larger sum than it was at all likely would be available as his recompense. Even if this difficulty were overcome, it was thought to be undesirable that at the head of the organization for clinical teaching there should be one who had, from the conditions of his appointment, restricted the field of his experience. It was thus felt that if whole-time professors were to be appointed in the departments of Medicine and Surgery, they would have to be young men of promise rather than teachers of experience, and it was not seen how these men could be supplied with an adequate amount of clinical material under the local conditions which prevailed.

Thus, while the Leeds teachers considered that in certain centres the formation of units on the general lines suggested by Sir George Newman might be conducive to the encouragement of research, and might also be accessory to the general teaching, they felt that some scheme should be devised which would act by improving the teaching opportunities enjoyed by the present staff and thereby secure the continuance of their whole-hearted co-operation in the education of the students. It is the duty of a medical school, whether it be associated with a university or not, to foster and to encourage research, and one test of the success of a university is the amount of work based upon research which it is able to show that it has put out. On the other hand, the schools and universities are charged with the great responsibility of educating and instructing students for the practice of their profession, and any arrangement which might lead to the teaching being carried out without the full benefit of the more experienced members of the staff was viewed with apprehension.

Even, therefore, at a time when it was thought that substantial financial support would be obtained from Government, a scheme was drawn up by Professors Wardrop Griffith and

Moynihan, with the co-operation and approval of their colleagues, which it was believed would meet the local conditions, would encourage research, and would improve the teaching of the students without involving any of the risks which have been mentioned above. This scheme has had to be somewhat curtailed in view of the vanished hopes of Government support; but, acting on the strong advice of the two heads of the departments of medicine and surgery, the Council of the University of Leeds, at a recent meeting, decided to adopt their modified suggestions. This decision has caused much satisfaction, and it is held to be one of the greatest steps that has been taken in connexion with the instruction of medical students in Leeds for many years.

The Leeds Tutorial Scheme.

The central feature of the scheme is the appointment of whole-time tutors—one on the medical and two on the surgical side. These appointments will have attached to them salaries of £500 a year, and this will involve the allocation by the university of £1,650 when the scheme of insurance is taken into consideration. A sum of £250 will provide the services of a lecture attendant and some extra clerical help, and the sum of £100 per annum will be allotted to each department for apparatus and for the provision of such things as lantern slides and diagrams. The university has, however, for some years paid £250 in respect of two part-time men who have acted as tutors, and as these will now be superseded, the net amount that the scheme will require is £1,850 per annum.

In the near future some mention may be made of the arrangements and improvements which it will be possible to carry out on the surgical side in connexion with these appointments. At present the teaching on the medical side will be discussed. Prior to the year 1910 the systematic lectures on medicine which were given at the School of Medicine numbered three per week and the course was spread over four terms. In the year 1910 the number of lectures which had to be attended by each student was diminished, they attended three terms instead of four. The students began their attendance on the lectures as soon after passing their second professional examination as was feasible. The lectures during the first term were of a general and introductory character; those during the next term were especially directed to the various systems such as the circulatory, respiratory, digestive or nervous. This part of the course was attended by infirmary students both in their first year of hospital study and in their second; and as the course during the second of the two terms never dealt with the same matter two years in succession things have worked well. It may be that in the future the number of terms during which the students are required to attend the systematic lectures will be reduced to two; but it is very strongly felt that it is eminently desirable that, when students have passed their examinations in anatomy and physiology, they should, at an early stage in their subsequent career, attend a course of medicine, carried out on the lines indicated, by one who occupies a senior position on the staff. It is felt that this cannot be replaced by any amount of tutorial instruction or by any kind of systematic instruction given by a junior man in the position of tutor.

Clinical Instruction in Medicine.

The clinical teaching at the infirmary (including that of the pathological department and the teaching of venereal diseases) will be regulated by a subcommittee consisting of the honorary physicians and assistant physicians, the pathologist, and the medical officer in charge of the venereal department, with the professor of medicine as *ex officio* chairman, and with the power to co-opt others. This power of co-opting will, it is hoped, lead to greater continuity of teaching, so that the instruction that a student has received in chemistry, anatomy, and physiology will be carried on into his clinical work instead of running the risk of being looked upon merely as milestones which have been passed.

The ordinary ward teaching will go on as at present; any alterations will merely be in the nature of improvements; any profound alteration in this the most characteristic feature of British hospital teaching would be matter for regret. Each teacher must, and should, go his own way, and should teach his students by the methods that he considers the best; his teaching may be didactic or Socratic; it may be conducted by the students being called upon to read the notes of the cases that have been allotted to them, and by

the subsequent discussion of the cases by selected members of the class, by the investigation and discussion of the symptoms and signs of the disease which are presented by the patients, or in any other way that the teacher may select. In relation with the diminution in number of the systematic lectures, it is intended to inaugurate a series of short courses of lecture-demonstrations of a clinical character by the various members of the honorary staff on the medical side. The number of lectures in each course, the subjects and the order of the courses, will be determined at a meeting of the above-noted committee. Each man will know a long time—it may be many months—beforehand what subject he is to deal with. In this way he can prepare for the successful result of his course by special study, by the preparation of diagrams and lantern slides under his own direction, and above all, perhaps, by the accumulation of suitable illustrative cases, in which he will be loyally assisted by his colleagues.

The Whole-time Medical Tutor.

The new officer will devote the whole of his time to the teaching of the students under the direction of the professor of medicine, who will act in concert with his colleagues, but care will be taken to secure for him a certain amount of time for research. He will conduct tutorial classes and supervise the men in their note-taking, and a very important part of his work will be the introduction of the junior students to their hospital work during the period of their preliminary clerkships. It is hoped that, by the appointment of newly qualified men as clinical assistants, the students may be encouraged to a fuller investigation of the cases entrusted to them, for there is no education so valuable as this.

It is intended that great care shall be exercised in the selection of the man to fill this position. He should have proved his ability to teach by having already done some teaching as a senior resident, for there is no considerable hospital where a senior resident has not the opportunity of teaching, and there are many men who have won their teaching spurs when acting in this capacity. He should either be qualified to come on the honorary staff in due course by the possession of the necessary degrees and diplomas, or he should be likely to become so. If and when a vacancy occurred on the honorary staff, a man who had held this position would be a very strong candidate if he had done his work well. Probably in a large medical school the ideal training for a position on the honorary staff of its hospital would be that, after a studentship at the school or elsewhere, a man should become a junior resident and go through his appointments preferably at the hospital concerned. He should then fill the senior position of resident medical officer, in this case by great preference at the hospital to which he hopes to become attached. This position he will probably hold for three or four years, and it will be during his tenure of office in all probability that he will decide to aim at consulting work and a position on the honorary staff. If after this training he is, on the recommendation of the honorary staff, elected to the post of medical tutor, he will, during the time he may have to wait for the occurrence of a vacancy on the honorary staff, have the greatest opportunity a man can have for enlarging his knowledge and experience for developing his teaching faculties and for legitimately paving the way to success in consulting practice, in connexion with his own school if he is fortunate to secure a position on the honorary staff, or elsewhere if the choice falls on some other candidate. The hospital will be manned chiefly by those who, for the early years of anxiety and for those years after a man ceases to be a resident but before he gets a position on the honorary staff, have been fortunate to substitute a period of years free from financial anxiety and endowed with the best opportunity a young man can have for developing his faculties and preparing himself for service on the staff.

To secure the fullest advantage from the appointment of these three men—one on the medical side and two on the surgical side—an effort is to be made to provide an instructional block at the infirmary, but this will be dealt with in a later article, along with the arrangements for the surgical teaching.

THE second Uruguay National Medical Congress was held at Montevideo in October, 1921; among the resolutions adopted were one calling for a permanent committee to study anthrax and another recommending the introduction of chlorination for drinking water. The next congress will be held at Montevideo in 1925.

British Medical Journal.

SATURDAY, JANUARY 7th, 1922.

THE MOTHER TONGUE.

THE Departmental Committee appointed by the President of the Board of Education to inquire into the position of English in the educational system of England has issued its report.¹ This inevitably challenges comparison with the report on the teaching of classics reviewed in these columns a short time ago.² While most fully in sympathy with the objects of the English Committee, we regret that their excellent case was not stated more concisely. It might have been considerably condensed, and does not escape the charge of unnecessary repetition. A much shorter report would have been more arresting, and would have been far more widely read. Nevertheless, for those having the leisure, the knowledge, and the interest, it is an absorbing document, and much of it would serve as a model of English prose. A word of praise is due to the Stationery Office for the form in which the report has been produced—a convenient small octavo volume of some 400 pages.

The primary demand on our system of education, and especially of elementary education, must be for a good working knowledge of English. All medical men will therefore be in agreement with the aims of this Committee. The possession by all citizens of our empire of the power to speak and write pure, concise English is a direct and vital interest of all. The spread of this power through all the classes and nationalities that make up the commonwealth of British peoples could go far to remove those misunderstandings, prejudices, and aversions that prevent men of different race, religion, status, and colour from living at peace, goodwill, and healthful commerce one with the other.

But pure English can yield something more and richer than even such a vast practical gain. English has a literature which may be made a source of that mental health which is itself both the origin and the end of health of body. It was at one time pleaded that if the child were but well taught the three R's, his knowledge and enjoyment of the literature in his mother tongue could be safely left to take care of itself. It was claimed that while there are departments of literature closed to all who have not special parts and training, yet there remain also wells of English undefiled from which all may drink deep draughts of solace and refreshment. Surely there are many who so drink; yet while human nature remains as it is, the child that is father to the man will need encouragement, help, guidance and even restraint in his reading. *Vide meliora proboque, deteriora sequor* is as true of the young as of the old. The heirs of all the ages must be prepared for the appreciation and wise use of the legacy that is theirs.

Happy indeed are those boys and girls who grow up in homes where that heritage is cherished, where the levity and perversity of the bastard jargon that has arisen in our great cities is avoided as something unclean and corrupting. We may reasonably rejoice that there is an increasing number of such homes in every class: but other influences are at work. The street and the music hall contribute the flippauey and distortion of

urban and exotic slang, and against this evil influence the school must strive. Yet even the school itself is not without its contribution to the complexity of the problem. At many schools, for instance, is still taught a language called "Commercial English," against the hideous solecisms of which the great business houses are, to their honour, emphatic in their protest in this Report: from its bondage they implore to be delivered. Nor is it only in the affairs of business that the gift of simple and straightforward writing needs cultivating. All who had to censor letters of our soldiers during the war—and this was a task that fell at some time to nearly every medical man of military age—must have been struck by the extreme illiteracy of the great majority of the troops. Men known to be intelligent, prompt, and responsive in regimental life became almost inarticulate when they tried to put their thoughts on paper, till at last it became the rule for meaningless formulae to be substituted for any expression of real feeling. The men were shut off from those they loved at home by a barrier, the impassableness of which can hardly be realized by those to whom writing is as easy and normal as speech.

The Committee has summarized its principal conclusions and recommendations in 105 propositions, arranged in sixteen sections. We cannot pretend to follow it through all these sections, the majority of which deal with matters that directly concern teachers, head masters, and professors. We would confine our attention to two points only: one is the recommendation "that care should be taken to insist on the accurate use of the English language by pupils specializing in mathematics or natural science." In the body of the report, after insisting on the universal importance of English at all ages the Committee goes on to observe that "in understanding and in expression, as in all else, it is the business of the university to crown and complete the effort of the school." Whether the student, the report continues, "reads literature or natural science, theology or history, or philosophy he will need the fullest command of the highest resources of his own language if he is to learn all that books and teachers in his subject can give him, and to make it a possession of his own. English, then, is needed in every faculty. It is the one subject which for an Englishman has the claim of universality. Without it he cannot attain to full powers either of learning or of teaching in any." "English is not merely an indispensable handmaid without whose assistance neither the philosopher, nor the chemist, nor classical scholar can do his work properly. It is one of the greatest subjects to which a university can call its students." These views are reinforced by a quotation from the report of the Natural Science Committee, which insisted that: "All through the science course the greatest care should be taken to insist on the accurate use of the English language, and the longer the time given to science the greater becomes the responsibility of the teacher in this matter. The conventional jargon of laboratories, which is far too common in much that is written on pure and on applied science, is quite out of place in schools. . . . Some literary study, including English, should have the first claim on the balance of the time of all science students."

The other point to which we would direct attention is that contained in the last recommendation—namely, "That in all schools the reading of the Bible should not be confined to the time set apart for religious instruction, but that its claim upon the time devoted to English studies should also be recognized." There is undoubtedly a decline in the practice, once almost universal, of reading the Bible; the origin and cause of this decline we cannot discuss, but the Committee is certainly right in affirming that on the score of the survival of virile and sonorous English alone—basing

¹ The Teaching of English in England. Published by His Majesty's Stationery Office, Imperial House, Kingsway, W.C.2, 1921. (Is. 6d. net.)
² BRIT. MED. JOURNAL, September 21st, 1921, p. 495.

the case only on that ground—the decline ought to be arrested, unless there is inevitably to be inflicted great injury, not only on the language itself, but on the power of appreciation of that English literature of which the Authorized Version is an essential and organic part. Professor Huxley, who was certainly no advocate of Biblical doctrine, foresaw most clearly the effect of this neglect, and was an ardent supporter of the study of what is, even as literature, something far more than the greatest work of translation in any language.

Let us think, if we can, of the state of the Englishman who has never read of the war horse that "sinclleth the battle from afar off, the thunder of the captains and the shouting," who has never heard of the time "when the morning stars sang together, and all the sons of God shouted for joy," in whom there is no awakening of old memories with the words, "He maketh me to lie down in green pastures, He leadeth me beside the still waters," and for whom "while I was musing the fire burned, then spake I with my tongue," conveys no association. Surely he can be no true Englishman for whom these things mean nothing. A great authority on English has said that "when a nation has achieved this manner of diction, these rhythms for its dearest beliefs, a literature is surely established." Many writers had worked to this end before the appearance of the English Bible, but that great achievement, setting a seal on all, set also a seal on our national style. It has its cadences, homely and sublime, yet so harmonizes them that the voice is always one. "Simple men," says Sir A. Quiller-Couch, one of the members of the Committee, who doubtless had much to do with the report, "holy and humble men of heart like Izaak Walton and Bunyan, have their lips touched and speak to the homeliest tune. Proud men, scholars—Milton, Sir Thomas Browne—practise the rolling Latin sentences; but upon the rhythms of our Bible they, too, fall back—'The great mutations of the world are acted, or time may be too short for our designs.' 'Acquaint thyself with the Choragium of the stars.' 'There is nothing immortal but immortality.' The precise man Addison cannot excel one parable in brevity or in heavenly clarity; the two parts of Johnson's antithesis come to no more than this, 'Our Lord has gone up to the sound of a trumpet; with the sound of a trumpet our Lord has gone up.' The Bible controls its enemy Gibbon as surely as it haunts the curious music of a light sentence of Thackeray's. It is in everything we see, hear, feel, because it is in us, in our blood."

The report rightly ends with an eloquent appeal for the wider, earlier, and better study of this best and most accessible of all English literature, a literature so rich and so accessible that we may, without irreverence, repeat of it the words, "Ho everyone that thirsteth, come ye to the waters, and he that hath no money, come ye, buy, and eat."

THE CLINICAL SIGNIFICANCE OF PAIN.

WHEN a disease is attended by pain, this one symptom is likely to surpass all others in the patient's estimation. Yet it is often the most baffling and misleading symptom to the doctor, so much so that we are sometimes tempted to belittle it and suspect that our patients are guilty of exaggeration. Even then we cannot always ignore it or persuade our patients to stop telling us about it. Dr. Henry Head's efforts to explain the causation and significance of pain are a welcome contribution to clinical medicine, and his address to the Sheffield Medico-Chirurgical Society, published this week, will, we feel sure, be read by all of us with interest. In it he has summarized in a very helpful way the known physiological facts regarding pain sensations, and has set out some important points in their interpretation. Some other aspects of the

subject were discussed in an article on the physiology of pain published last year.¹

His address deals particularly with pain of visceral origin. So long as the internal organs are discharging their functions normally the afferent impulses which they may originate do not enter consciousness. This Dr. Head explains by suggesting that the cerebral cortex, which is responsible for the discriminative functions of sensation, exercises a dominant influence over the lower centres, represented by the optic thalamus, whose reactions are impulsive and urgent. These impulsive reactions may be evoked either by a noxious stimulus, which reaches a high enough grade of intensity to overcome the inhibition of the cortex, or by disease or injury interfering with the paths through which the cortex normally exerts its control. But even when no such interference exists there is reason to think that "once the path has been opened and the dominance of the higher centres overcome a weaker visceral stimulus will be followed by sensation," so that long continued visceral irritation may give rise to pain from apparently inadequate causes. Certain general bodily states may produce a diminution of automatic control, so that not only will a weaker stimulus cause painful sensations, but there may be a diffusion or spread of visceral pain and tenderness beyond the areas normally involved. It is important to appreciate this possibility, since it throws light on those puzzling cases in which the extent of the pain or tenderness appears disproportionate to the exciting cause. As examples of this Dr. Head mentions conditions in which the stimulus is extremely severe; as in gall stones or renal colic, or a referred pain becomes chronic; so that not only is the resistance of the patient worn down by the disease, but the repetition of painful impulses facilitates their passage. Menstruation, anaemia, and debilitating psychological states, such as worry or emotional shock, may produce similar effects.

Putting on one side, however, these instances of undue generalization of painful sensations, much valuable information is to be gained from careful study of superficial pain and tenderness. It has to be determined whether tenderness of the parietes is due to the deep or superficial structures, and whether it has a local significance or is a manifestation of referred pain. The criterion appears to be that, if the pain is referred, superficial tenderness will be found corresponding to the posterior portion of the segmental areas affected. These areas of superficial hyperaesthesia are well enough known in connexion with gastric ulcer, but their study has not been carried as far as it might have been by clinicians. To interpret these referred pains a knowledge of the relation of afferent impulses to the segments of the central nervous system is necessary. Considerable contributions have been made to this study by Sherrington and by Head himself. Sherrington's work is only influencing our textbooks slowly, far too slowly indeed. In books devoted to the nervous system it meets with due attention, but internal medicine as a whole has not sucked out the full advantage from it. The task of correlation is difficult, as Head admits, but it should be done. One striking example is worth quoting; it relates to the distribution of referred pain in heart disease. Certain abnormal conditions of auricular tension, Head observes, can produce pain and tenderness of the skin supplied by the sixth and seventh thoracic segments: disease of the aorta and ventricle may be associated with similar areas higher up on the chest, in the region of the third and fourth cervical. The explanation of this can be found in the embryological development of the heart. Its afferent visceral innervation is upside down in relation to the present position of the adult organ. At one stage in its

development the heart consists of a single tubular vessel divided into three chambers, of which the hindmost becomes the auricle, the middle portion the ventricle, and the anterior, or headmost, the ascending arch of the aorta. Affluent impulses from the heart enter the segments of the central nervous system just as if the auricle were still the hindmost organ. Moreover, the segments concerned with cardiac innervation jump from the fourth cervical to the first or second thoracic, omitting the upper limb, which has budded out at a later stage of development.

Clearly the time has come for a new book on applied anatomy and physiology which shall do for internal medicine what Holden's *Landmarks* did for the surgery of a former generation. Will Dr. Head give us his book of landmarks in similar compact shape?

THE COMPANY OF THE BLIND.

THERE are many upon whom severe affliction falls who bear their loss with noble fortitude. There are a few to whom it is given to turn their loss into a gain, at least to others. The late Sir Arthur Pearson was one to whom it was given in superabundant measure to redeem his physical affliction by the labour for others that came of his affliction. A man of intense energy and great capacity, he had proved his powers in one of the most difficult fields of life—that of daily journalism. Smitten with blindness in the heyday of his success, his blindness seems not to have brought home to him his own deprivation so much as the deprivation suffered by all the company of the blind. The energy which he had exhibited in his profession of journalist was diverted to the organization of measures for the betterment of the blind. Before his day there were many and excellent institutions for the training and assistance of the blind. Yet there seemed to cling to the public mind much more the familiar legend, "Pity the Poor Blind" than an appreciation of the possibilities of usefulness so often demonstrated by blind persons. Sir Arthur showed in his own person that pity was less worthy or desired than a recognition of capacity for service. In that he did a great thing—it is the greatest debt the company of the blind owe to him.

Of his works for the blind, St. Dunstan's for the training of blinded sailors and soldiers stands in the forefront in public appreciation. In earlier days his blindness would have been justified as "providential," so greatly did its effects meet the exceptional needs arising out of the war. It was little less than a re-education itself for a blinded youth to meet a blinded man who had shown how greatly life still mattered. But no less important and of more permanent interest will be the effects of his administration at the National Institute for the Blind. This is nothing less than the university of the blind, not only of this country, but throughout the commonwealth of nations within the British Empire. It prints in Braille and circulates a wealth of books, and there is no boon so precious to the blind as a book. It arranges training for those past school age, and itself is responsible for two colleges, for boys and girls respectively of the professional class, and for a home for blinded infants. Besides, it is the "Equire Within" of the blind, for there is no position of difficulty arising in the life of a blind person in which some help and leading cannot be given from the institute.

To secure these institutions upon a satisfactory basis it is proposed to raise a fund as a memorial to Sir Arthur Pearson. One-third of the fund will go to St. Dunstan's; one-third to the National Institute for the Blind; and one-third for division amongst all other recognized charities for the blind throughout the Empire.

Doubtless the inclusion of these other charities within the scope of the fund will lead to a working arrangement amongst all of them so desirable in the best interests of the great cause they are designed to serve. But before any allocation is made from the fund 2½ per cent. of the total will go to the "Fresh Air Fund," the earliest of Sir Arthur's public interests, and one which has brought spells of happiness to thousands of little ones whose homes in our great cities afford no glimpse of woods and pleasant pastures. Queen Alexandra has become Patroness of the fund, but even without that endorsement we feel that the purpose of this memorial will appeal to many of our profession, who best know the needs of the blind.

THE NEW YEARS HONOURS LIST.

THE honour in the New Year's List which will most certainly command the universal applause of men of science, and of members of the medical profession in particular, is the G.B.E. to Dr. C. S. Sherrington, Professor of Physiology in the University of Oxford. Its conferment at the present time is no doubt related to the fact that he is President of the Royal Society, but were State honours always given in direct recognition of the recipient's achievements and the distinctions he has conferred on his country, this one would have been given earlier. The honour of knighthood is conferred upon Dr. George Scaton Buchanan, C.B., senior medical officer of the Ministry of Health, and British representative on the League of Nations Health Conference and on the Office Internationale d'Hygiène Publique. Sir George Buchanan, whose father was principal medical officer to the Local Government Board, joined the medical department of that Board in 1905, and was at one time chief inspector of foods and chief assistant medical officer to the Board. During the war he rendered important services to the army, holding the rank of honorary lieutenant-colonel R.A.M.C.; he was a member of the War Office committees for the prevention of disease, and of the Medical Advisory Committees for the Mediterranean area and for Mesopotamia. The same honour is received by Mr. John Herbert Parsons, F.R.C.S., F.R.S., surgeon to the Royal London Ophthalmic Hospital and ophthalmic surgeon to University College Hospital, whose researches into the pathology of diseases of the eye have made his name well known both to physiologists and practitioners; by Dr. George Stewart Abram, senior physician to the Royal Berkshire Hospital and Mayor of Reading in 1918-20; and by Mr. J. W. Thomson Walker, F.R.C.S., lecturer on urology at King's College Hospital. The K.C.B. (military) is conferred on Major-General C. C. Manifold, a distinguished officer of the Indian Medical Service, who received the C.M.G. for services during the war; and on Group Captain (Acting Air Commodore) Matthew Henry Gregson Fell, C.M.G., until recently Medical Director to the Royal Air Force Medical Service. Surgeon Rear Admiral William Bett, M.V.O., principal medical officer of the Royal Naval Hospital, Haslar, receives the C.B. Dr. Robert Thomson Paton receives the C.M.G. in recognition of his services as Director-General of Public Health and President of the Board of Health, New South Wales. The C.I.E. is awarded to Major-General John Blackburn Smith, C.B., I.M.S., Deputy Director, Medical Service, Eastern Command; Lieutenant Francis Hope Grant Hutchinson, I.M.S., Public Health Commissioner with the Government of India; Lieutenant-Colonel James Eutrican, I.M.S., Inspector-General of Civil Hospitals, Burma; Lieutenant-Colonel Robert Fraser Standage, I.M.S., Residency Surgeon in Mysore, Bangalore; and Khan Bahadur Nasarvaaji Hormasji Choksy, retired medical officer, Bombay Municipality. Dr. John Oldershaw, Mayor of Wallasey in 1911-12, receives the C.B.E. for public services in Liverpool and district. The Kaisar-i-Hind medal (first class) is conferred on Lester Hayes Beals, American Marathi Mission, physician and surgeon, Bombay, and the Rev. Frederick Vincent

Thomas, M.B., C.M. Edin., Baptist Medical Mission, Palwal, Gurgaon District, Punjab. We note with pleasure that the honour of knighthood has been conferred on Colonel Joseph Reed, chairman of the Press Association and managing director of the *Newcastle Chronicle*, who took a great interest in the preparations for receiving the British Medical Association at its annual meeting in Newcastle last summer.

MEDICAL INSURANCE AGENCY.

A MEETING of the Committee of Management of the Medical Insurance Agency was held on December 9th, 1921, when the chairman, Dr. G. E. Haslip, presented an interim report dealing with the business transacted during the nine months ended September 30th, 1921. The business of the agency showed a steady increase in all directions. During the period under review eighty-four policies in life assurance had been negotiated, the contracts being spread over a group of offices of the highest standing, thus continuing the principle of combining security for the assured with complete freedom of action for the agency. The advice which should be given with regard to motor car insurance has been very carefully considered in view of the fact that not only have all the leading offices increased their rates, but in the case of cars of small horse-power have begun to enforce a minimum rate—for example, a car originally costing £400, the value of which, owing to use and age, has decreased to £250, is assessed in premium at the same rate as a new car of similar horse-power and a value of £400. The explanation offered by the principal company accepting these risks was that for some years offices granting motor car policies had steadily lost money, the losses in 1920 being somewhat serious. Naturally the cost of repairs and replacement of parts and the "third party risk" are the same whether a car is new or old. Further, it was found that a large percentage of the claims arising under motor car policies related to the smaller horse-power cars; it appears, therefore, that the higher rates must be regarded as equitable. The agency lays itself out to give advice to clients with regard to all forms of policies, and in recent times has freely been consulted with regard to household policies; the advice given has been to take out the full comprehensive policies now issued by all the leading offices, which in addition to the usual risks covered by fire, burglary, and workmen's compensation, also include special perils, such as riot, civil commotion, strikes or labour disturbances, damage to household goods, etc., arising from burst or overflowing water tanks, apparatus, or pipes, damage to mirrors, and liability to the public, etc. The tariff offices do not grant policies securing medical men against larceny and thefts committed in the surgery or waiting-room—a risk to which general practitioners are particularly liable; the agency has been able to arrange with Lloyd's underwriters to grant policies which secure a medical man against these risks. The agency is always ready to reply to inquiries, and is in a position to advise medical men as to policies best adapted to their special needs. The Chairman stated that the sum in hand available for grants to medical charities was £1,055. The following interim grants were made: To the Royal Medical Benevolent Fund, the Royal Medical Benevolent Fund Guild, and Epsom College Benevolent Fund £315 each; to the Royal Medical Benevolent Fund Society of Ireland and to the Birmingham and Lincolnshire Medical Benevolent Societies £25 each. These grants raise the total so distributed in 1921 to £2,000; the total sum voted to medical charities by the agency since its foundation amounts to £3,400. This very substantial contribution to the charities of the profession is in addition to the rebates made to insurers, which amount to over £10,500. On the ground alone of the grants made to charities we venture to express the hope that members of the profession who are thinking of taking out new policies will consult the Medical Insurance Agency, which, by the courtesy of the British Medical Association, has its offices at 429, Strand. By so doing they will both advantage themselves and benefit less fortunate members and their widows and orphans.

RESEARCH WORK IN AVIATION.

Is our recent notice of the first *Report on the Health of the Royal Air Force* (BRITISH MEDICAL JOURNAL, December 31st, 1921) reference was made to the research work that had been carried on both in this country and in India, where much of the flying is done under war conditions. During 1920 the total number of examinations made in this country by means of the special tests to determine flying fitness was 674, and of these more or less picked individuals 207 were rejected, 78, or 38 per cent., failing on account of defective physical efficiency, and 49, or 24 per cent., for visual defects. The ten tests for physiological assessment include: the pulse rate, at rest, and response to graduated exercise together with rate of return to normal; measurement at rest of systolic and diastolic blood pressure; presence of tremor of eyes, tongue, and fingers; degree of ability to balance on either leg for fifteen seconds; degree of ability to raise a rod on a board from a table to the shoulder level; the character of the knee-jerk; the vital capacity; the length of time that the breath can be held after full expiration and full inspiration; the height to which a column of mercury can be forced with the lips and cheeks held; and the fatigue test—the length of time that a column of 40 mm. of mercury can be sustained with the breath held after full expiration and full inspiration, together with the nature of the pulse during this time. In addition, in the case of candidates with a history of train or swing sickness or of ear disease the rotatory chair was used, and in the re-examination of flying officers the measurement of reflex times was undertaken. In the preliminary examination it was, generally speaking, found that a history of aptitude at sports demanding co-ordination of eye and limb is of the same value as a comparatively elaborate test carried out on a special occasion in circumstances rather trying to the candidate. The causes of rejection, apart from visual, aural, nasal, and throat defects, were generally conditions of the respiratory, circulatory, and nervous systems, which have been found to be absent in successful pilots and present in pilots who broke down, such as poor vital capacity, low diastolic with a high pulse pressure, poor response of the pulse to graduated exercise, tachycardia, and tremor and other signs of deficient nervous control. It is interesting to note that the average of post-war results obtained by these tests is higher than those given during the war; this difference is attributed to the influence exerted by the nervous strain of war conditions. Investigations in India did not lend any support to the view that some unexplained accidents to pilots who had suffered from malaria were due to loss of control owing to an acute attack of the disease while flying. But evidence is accumulating to show that malaria and its sequelae, and possibly the administration of quinine in this connexion, are closely related to the development of oxygen want and flying stress at high altitudes. There is, however, no reason why, after malaria has been thoroughly treated, a pilot should not be in every way as efficient as before. After residence in any station in India there is a lowering of the physical efficiency reached in England; the strain of frontier flying is considerable, and there is also the liability to various infections and fevers. The onset of failing health is revealed by the efficiency tests, which give better results in new arrivals and in winter than in summer. From the experience gained in more than 300 detailed examinations of the personnel at various Royal Air Force stations in India some slight modifications in the standards of the efficiency tests are recommended. The effects of glare are considered under the headings of subjective and objective effects; in connexion with heterophoria it is stated that at present few pilots suffer in any marked degree from this condition, and that although bumpy landings are not uncommon few minor flying accidents can be ascribed to inco-ordinated ocular muscular balance. A remarkable point brought out by routine eye examination is the peculiar reaction so consistently found to the official Air Force test for true judgement of distance (the orthostereometer). Even when tests for convergence and heterophoria are normal, the readings as to judgement of distance often vary in a noticeable manner.

ably the explanation of this feature of the orthometer readings may be found in the effect of glare: in producing a tonic or clonic spasm of the ciliary muscles, with slight variations in the thickness of the lens, this would also cause a state of alternating myopia and hypermetropia, so the abnormal readings observed. There is, however, no evidence that a mental factor also plays a part.

INCUBATION AND CONTACT CARRIERS OF ENTERIC FEVER.

The existence of incubation carriers, meaning by this phrase persons who pass the infecting organisms in their excreta during the incubation period and before symptoms of enteric fever appear, has been assumed by some writers, but the idea is not received much support in this country. In 1915 Colonel D. Harvey failed to isolate the bacilli from the faeces of urine of patients before the end of the first week of enteric fever, and concluded that, entering by the mouth, the bacilli gain a footing in the bile passages, where they multiply, and then invade the lymphatic system and blood stream. According to this view the specific organisms would not appear in the excreta until clinical evidence of infection was obvious, and therefore incubation carriers would not occur. Dr. William Fletcher,¹ Bacteriologist to the Institute for Medical Research, Kuala Lumpur, Federated Malay States, records an accidental infection of several men with *Bacillus paratyphosus B*, which conforms to the alternative view that the typhoid and paratyphoid bacilli when taken by the mouth multiply rapidly in the small intestine and are excreted in the faeces, invasion of the blood stream and the onset of symptoms occurring later. Three carriers of dysentery bacilli were being treated with gruel containing a lactose-fermenting streptococcus; the gruel became accidentally contaminated with *B. paratyphosus B*. The men's stools were examined daily; within a fortnight they were found to contain the latter organism, although none of the men at that time exhibited any symptoms of that infection; two of them, three and nine days after the isolation of bacilli from their faeces, were taken ill with paratyphoid fever, and were therefore incubation carriers. The third man never had any such symptoms, and was merely a contact carrier. Agglutinins were absent from the blood at first, but appeared later in all three of these carriers. Dr. Fletcher mentions other cases of contact carriers of paratyphoid bacilli, and confesses that he formerly (1917) accepted the interpretation that the specimens of faeces had somehow been mixed with the excreta of a chronic carrier. In the light of further experience he would regard such cases as transitory contact carriers, comparable to those widely recognized in diphtheria and cerebro-spinal fever. Although the bacilli of chronic typhoid carriers have been found to be as virulent as those of acute cases, there is some reason to think that these of contact carriers are diminished in virulence, and possibly the decline of an epidemic may be due not only to the production of immunity but to the comparative harmlessness of bacilli which have passed through a series of healthy contact carriers. The immunity of the seasoned laboratory worker and the old resident in an endemic area when they have not had the disease may be due to immunization induced by a transitory contact carrier state, for in many of them there are immune bodies in the blood.

THE RELATION BETWEEN MENTAL AND PHYSICAL EFFICIENCY.

DR. ALFRED A. MUMFORD read before the Manchester Statistical Society, on December 14th, 1921, a paper relating some of the results of a research work he has undertaken to determine the relation between mental and physical efficiency of boys at the Manchester Grammar School. The need for scholars and others of sedentary habits to take bodily exercise in order to maintain a proper condition of health was recognized and taught by the very earliest physicians of whom there is any record; and the diversity of character and capacity among different individuals was tacitly recognized in the

ancient doctrine of temperaments, which taught that the greater activity of certain parts of the human body—the liver, the spleen, and the brain—gave individuals their distinctive qualities. Modern research into the capacity of school children shows a marked correlation between certain physical attributes, notably the respiratory function, and the general physical and mental fitness of the subject. The simplest individual act of intellectual attention involves a diminution of bodily movement, and therefore in the range of breathing. Extreme attention is often correctly described by the term "breathlessness." Recovery from the effects of prolonged attention is accompanied by a deep sigh, and one of nature's most potent methods of relief is by laughter which causes a series of violent diaphragmatic movements. Dr. Mumford had noted the close relation between the improvement in health and respiration of a group of rickety children under continuous treatment. As their breathing powers became developed their attacks of fearfulness and their night terrors disappeared, and they voluntarily associated with their fellows in the games and romping. He thought it worth while to see whether the conclusions about the intimate association between the range of breathing and vigour would shed light on the capacity of boys at the Manchester Grammar School to withstand the stress of indoor and prolonged study, and to inquire whether there was any intimate relation between school attainment and respiratory capacity. The boys were classified in four groups: brilliant, above average, average, below average, according to the judgement of the form master, checked by the terminal report. Boys in different education grades were examined, including a group of new boys. The first calculations of respiratory efficiency were carried out, according to the method of Professor Dreyer of Oxford, by measuring the largest amount of air a person can exhale after deep inspiration, or the "vital capacity." The comparison between the respiratory grading and form masters' reports showed that there was a marked relation between respiratory grading on Dreyer's method and school attainment at the early ages of school life, but this became less marked at the later ages of 16 to 18, the probability being that the more robust boys formed a smaller proportion of the whole number at the higher ages. It was also found that intensive study for examination tended to reduce the respiratory power, but that this was fully recovered after a holiday. His experiments led Dr. Mumford to attempt the measurement by the direct record of the movement of the chest wall. The test was in the nature of a persistence test. The time was noted during which a boy could hold his breath against a column of mercury some 40 mm. in height. It is a test of will as well as of physique. In a class in the middle school the five top boys of the class held the mercury for an average period of thirty-three seconds, the five bottom boys for nineteen seconds only. In the matriculation forms the five top boys held it for thirty-one seconds, the five bottom for twenty-five. In order to introduce an element of competition a number of boys were made to repeat the test before the whole class; it was then found that the best boys bettered their record, and the worst boys failed to attain their previous standard. It seemed as if the top boys often had powers in hand which they could use in emergency, and that the less successful either could not or would not exert themselves further. "This," we are told, "is something allied to what Sir James Mackenzie has called the reserve power of the heart, and may, for the time being, be designated as vital resources." The research is distinctly suggestive, and will no doubt attract the attention of school doctors. It appears from the diagram in the paper that the apparatus used is an adaptation of the sphygmometer, a jacket being substituted for an armlet.

A COURSE FOR SCHOOL MEDICAL OFFICERS.

WE are informed that the London Hospital Medical College has arranged a special course of instruction in the work of school clinics and on diseases of children in order to provide the necessary training for junior practitioners proposing to

¹ *Incubation and Contact Carriers of Enteric Fever. Studies from the Institute for Medical Research, Federated Malay States. Kuala Lumpur:*

undertake work (whether part-time or whole-time) under the School Medical Service. The course will begin on February 1st and extend over six months; at its conclusion certificates of efficiency will be issued to those qualified to receive them. An introductory lecture will be given by Sir George Newman, Chief Medical Officer of the Ministry of Health and the Board of Education. The syllabus includes lectures and clinical instruction by members of the London Hospital staff in the general welfare of children; diseases of the ear, nose and throat; diseases of the eye; and diseases of the skin, including the x-ray treatment of ringworm. Lectures on the hygiene of schools, with visits to school buildings, will be given by Dr. C. J. Thomas, Principal Assistant Medical Officer of the London County Council. The course is not restricted to former students of the London Hospital, but the number of those attending it will be limited. The fee is 20 guineas, and applications should be forwarded to the Dean, Professor William Wright, London Hospital Medical College, Mile End, E.

THE STEWART LECTURES AT MELBOURNE.

THE first course of Stewart Lectures before the University of Melbourne were delivered in 1911 by Professor Osborn on "Climatology"; the second, in 1913, by Dr. Breinl, on "Tropical medicine and conditions affecting white settlement in tropical Australia." The courses were suspended during the war, but resumed last November, when Dr. R. J. A. Berry, professor of anatomy in the university, gave a course of three lectures on "The modern psychology." The lectures owe their origin to a bequest of over £25,000 made by Dr. James Stewart, F.R.C.S.I., who as a young man emigrated from the north of Ireland and practised in Ballarat from 1853 to 1876. He was one of the original honorary medical officers of the Ballarat Hospital and was the second mayor of Ballarat West. He retired to England and died on June 30th, 1906, aged 76. He had made a large fortune, founded on success in practice and extended by fortunate mining investments. He left a bequest of £25,000 to the University of Melbourne, and with it were founded the University's Stewart lectures in medicine and in surgery, its Stewart scholars in anatomy, in medicine, and in surgery, provision was made for apparatus in these and other departments, and a biennial course of Stewart lectures on some subject of national importance to Australia was instituted. In addition, the same benefaction enabled the University indirectly to appoint its Stewart lecturers in anatomy and in pathology, and assisted in the appointment of a lecturer in physiology. Provision was also made out of it towards a future department of neurology. In addition to his bequest to the University, Dr. Stewart left large sums to educational institutions in Ballarat and to Trinity, Ormond, and Queen's Colleges for theological purposes. Professor Berry began his course by accepting McDougall's definition of modern psychology as the "positive science of the behaviour of living things." Every living thing, he said, reacts to stimuli derived from the internal bodily or somatic world and the external physical world. The mode of reaction constitutes behaviour, which depends on the number and nature of the incoming afferent impressions, and the number, nature and relative state of development of the brain cells or neurones. He devoted his first lecture to a consideration of the evolution of a brain throughout the ages as the physical organ of the mind. In his second lecture he considered the view that the cessation of general education in the masses at the most critical period of life was unfortunate, since brain centres little used do not develop normally. He described three types of head abnormality. In every school, he said, not far from 2 per cent. of the children were small-headed, and had a grade of intelligence which, however long they lived, would never develop beyond the intelligence of a child 11 or 12 years old; they could be taught a certain amount of rote learning, such as to read and work simple arithmetic, but could not be

taught to meet new conditions effectively, or to think, reason, and judge as normal people do. In the second type of abnormality the head was big; in the third were classed super-intelligent children, who were as approximately numerous as the "feeble-minded." Such children were apt to be misunderstood by teachers, and unless given a class of work which called forth their best efforts, ran the risk of falling into lifelong habits of submaximum efficiency. Professor Berry concluded this lecture by describing his method of diagnosing cerebral under-development in childhood and of establishing a prognosis of future adult social inefficiency. The third lecture dealt with the psychological failures of life. Pronounced cases of idiocy, mongolian imbecility, and cretinism could, Professor Berry said, easily be recognized even by a layman, but they constituted only from 20 to 30 per cent. of the total number of mentally defectives. The remaining 70 per cent. could only be diagnosed by specially trained experts. Professor Berry concluded his course by urging the need of the establishment in Australia of an institution for the scientific study of the child.

VIENNA.

SOME inquiries received as to post-graduate courses in Vienna, and conflicting statements as to the fees for such courses and the cost of living in Vienna, induced us to ask for information from Professor Wenekebach, director of the first medical clinic in the University of Vienna, who visited this country shortly after the armistice to enlist sympathy with the position of the Vienna population and university. Professor Wenekebach's reply, in which he gives some general particulars, is published elsewhere in this issue. The full programme, which is much too long for reproduction, shows that the arrangements for the first three months of 1922 are very elaborate; they include courses in medicine, children's diseases, neurology and psychiatry, surgery and orthopaedics, as well as in various specialities; there are courses also in pathological histology, bacteriology, and the preparation and use of serums. The courses last for various periods from a fortnight upwards, and we gather are so arranged throughout the day that several could be attended during the same period. The fees vary; we observe a course in metabolism for which the fee is 10,000 kronen, and another in the use of the bronchoscope and oesophagoscope in which it is 200,000 kronen. Professor Wenekebach is no doubt justified in saying that prices in Vienna are wild; in recent months the rate on Vienna has generally been quoted as 10,000 to 12,000 kronen to the £, but on one day last week business was actually done at 23,000 kronen to the £. At the same time we observe that in the case of some courses no fixed price is mentioned and that the fee is a matter of arrangement between teacher and taught. It will be seen that foreigners attending the Vienna post-graduate courses must sign a declaration to the effect that they disapprove of the exclusion of German-speaking doctors from international congresses, and that Professor Wenekebach talks of the University of Vienna as still a German university. We had supposed that it was an Austrian university using the German language, and we would be inclined to think that Vienna would be well advised not to identify itself too closely with the German State. Germany still seems to be disposed to maintain its reputation as the arch-mischief-maker of Europe. German is the mother tongue of nations other than those included in the German State, and we conceive the way to approach this matter, in the beginning at any rate, is to ask for discrimination between nationalities in this respect.

THE Lettsomian lectures before the Medical Society of London will be given by Sir Leonard Rogers, C.I.E., on January 30th, February 8th, and February 20th at 9 p.m., the subject being "Amoebic Liver Abscess: its Pathology, Prevention, and Cure." The annual oration will be delivered by Mr. H. J. Waring, C.B.E. The anniversary dinner of the Society will be held at the Wharfedale Rooms, Hotel Great Central, on Wednesday, March 8th.

GLASGOW UNIVERSITY.

[Annan, Glasgow.

NINETIETH ANNUAL MEETING

of the

British Medical Association,

GLASGOW, 1922.

THE UNIVERSITY OF GLASGOW.

THE LATE SIR WILLIAM
GAIRDNER, M.D.,
President of the British Medical
Association, Glasgow, 1922.

GLASGOW is justly proud of its university. In the series of articles on the city which we intend to publish from time to time the first place must be given to that great institution. The University had its origin in mediæval times; in antiquity it is second only to the Cathedral, and it was a dominant influence long before Glasgow became a municipality.

The history of the University has been divided by Mr. Coutts, its latest and best historian, into periods of approximately a century each: the first from the founding of the University in 1451 to the Reformation, the second from the

Reformation to the Revolution, the third from the Revolution to the end of the eighteenth century, and the fourth the nineteenth century and later. In this sketch we can only indicate some salient features and perhaps whet the appetite for more information.

Origin of the University.

The University of Oxford came into being in the twelfth century, Cambridge early in the thirteenth century, St. Andrews in the beginning of the fifteenth century, Glasgow in the middle of that century, and Aberdeen at its close. These were all founded by the Church, and it was William Turnbull, Bishop of Glasgow, who obtained from Pope Nicholas V, whose five thousand manuscripts formed the nucleus of the Vatican Library, a Bull for the foundation of a *studium generale* in Glasgow. James II of Scotland was the first, however, to write of the "University" of Glasgow—"our most beloved daughter" were his words.

The universities founded by the Church were apparently of two types. The *studium generale* was governed by a guild. In Italy and in provincial France the guilds were guilds of students, and the *studia generalia* over which they ruled were "student-universities." In Paris, Oxford, and Cambridge the guilds were guilds of masters, and the type of institution was the University of Masters. Glasgow University, with Bologna as model, was to be a combination of the two systems; the head was to be the Chancellor, who was always to be the Bishop of Glasgow, and who was to delegate his power to the Rector, an office characteristic of the student-universities. The Rector was elected then, and still is, by the students, divided into four nations according to place of birth.

The death of the good Bishop Turnbull hindered the development of the scheme and the only faculty which really obtained a firm hold was the Faculty of Arts. This faculty in time became the most powerful body in the University. The Regent or Master of the Faculty of Arts was the head of the Pedagogium, a building situated in the Rottenrow, a once fashionable but now less than indifferent street near the Cathedral, and in it the students were compelled to live under very strict discipline and conditions not specially conducive to study. The students in time ceased to be members of the congregation and one element of the student-university thus disappeared. In 1460 James, Lord Hamilton, bequeathed to the "College of Arts" a tenement in High Street with four acres of land adjoining. And it was in buildings on this ground that the classes of the University continued to meet for upwards of four hundred years.

Second Period.

When the Reformation came, changes were inevitable in the teachers and in the government of the University, its members being Catholic clergymen and its revenues derived mainly from the Church. A period of profound depression and poverty followed and frantic efforts were made by the few remaining officers of the University to revive its fortunes

It was then that one of the greatest men that Scotland ever produced came to the resene. The learning, teaching power, and organizing capacity of Andrew Melville restored the University. Through his efforts it was raised again to the level of influence enjoyed in the most prosperous years of the Catholic period. It is generally believed that Melville played a notable part in formulating the provisions and regulations of the "Nova Erectio," a charter granted by James VI of Scotland in 1577, by which provision was made for the support of a principal who taught theology, the scriptures, and Hebrew, and three regents teachers of morals, politics, arithmetic, and geometry. At the Restoration the establishment of Episcopacy deprived the University of great part of its revenues, and the college was again reduced. The next twenty-eight years were years of further depression till after the Revolution, when again good fortune came and within another generation seven new professorships were founded or revived, amongst them medicine in 1712 (its original date is 1637) and anatomy in 1718.

The masters who taught subjects in the Faculty of Arts were known as Regents till about 1727, and each regent began with a class of freshmen, and taught them all the subjects of the curriculum till the end of their four years' course. The institution of separate professorships for individual subjects belongs to the eighteenth century. Students resided compulsorily within the college till the close of the seventeenth century, when the buildings were required for class-room purposes. When the last student in residence had to seek a home elsewhere he demanded and received a certificate from the Faculty that his expulsion was in no way a reflection on his conduct.

Third Period.

From the Revolution to the end of the eighteenth century the history is one of continuous progress and increase. Just before the Revolution the students probably numbered 120 to 150. In 1702 there were 400 students, and about this time the great influx of students drove the authorities to set about increasing the professorships and expanding the buildings. The story of the frequent appeals to the public and to the Sovereign of the day (often made directly) forms an interesting side-light on history. A group of distinguished teachers of world-wide fame adorns this period, the middle of the eighteenth century: Thomas Reid the Philosopher; Adam Smith, the author of the *Wealth of Nations*; William Cullen, Professor of Chemistry, then Professor of Medicine, and the founder of clinical teaching; Joseph Black of "latent heat" fame. Cullen had the additional merit of being the first to discard Latin and lecture in English. No less eminent were some of the alumni of this time: Smollett, Boswell, William Hunter, "Jupiter" Carlyle, the elder William Hazlitt, Dugald Stewart, Jamieson, the author of the *Scottish Dictionary*, and "Christopher North" were men of calibre fit to meet the great teachers on their own ground.

The Nineteenth Century.

In the first half of the nineteenth century the growth of the city in size and in importance, and its tendency to spread towards the west, left the University buildings in High Street isolated and surrounded by all the activities and turmoil of commerce, as well as inadequate in accommodation. In 1870 the great migration took place to the elegant Gothic building designed by Sir Gilbert Scott. On the site of the ancient University, after centuries of academic adventure,

there is now a noisy goods railway station; where once stood the pillared and domed Hunterian Museum there is now an underground railway station. Smoky and smelly. The casual visitor knows of the former glory of learning only from a bronze mural tablet on the railway offices with the inscription:

"On this site stood the University of Glasgow, 1460 to 1870. The main gateway re-erected at Gilmorehill stood opposite College Street."

The change to Gilmorehill was a most happy one. The graceful building facing south over the West End Park crowns the hill. Its tower is a landmark visible for many miles around. And from it one may see the Peaks of Arran, the rounded mass of "Tintock Tap," the rugged heights of "The Cobbler" and Ben Lomond, while the great stretch of the harbour and shipbuilding yards lies beneath, and the busy active city spreads out towards the east, murky and grey, its factory chimneys and church steeples projecting into the smoke-cloud. And so it comes about that the University

finds itself placed guardian-like in the midst of Glasgow's industry and commerce. The boom of the great bell as it strikes the hours mingles with the deep-toned whistle of the ocean liner in the river, and the siren of the shipbuilding yards penetrates even the quiet of the examination hall. Yet this close association of the University with the other Glasgow is no new one. In former days it exhibited itself in practical ways. The printing works of the famous Foulis Brothers were warmly supported by the University authorities, and when Robert Foulis conceived the idea of setting up an Academy of Fine Arts in Glasgow the University granted him the use of rooms for his students and the Faculty Hall for exhibitions. Wilson, Professor of Practical Astronomy, formerly a typefounder, still continued the business and transferred his foundry to a site within the University grounds. The most noteworthy example of assistance given by the University to struggling genius is in the case of James Watt, who lived in apartments and had a workshop in the College buildings and was permitted to style himself mathematical instrument maker to the University, though he never was a matriculated student. On their

FRONT OF OLD COLLEGE IN HIGH STREET, GLASGOW.
(From an old photograph.)

part, the citizens in the seventeenth and eighteenth centuries took a lively interest in the University, whose dwelling was in their midst and whose students in scarlet gowns lent a brilliant touch of colour to the grey streets. In the days of the "tobacco lords," and in the later era when the coalfields and iron works enriched the merchants, they recognized that the learning of the University was an older and further flung renown than that of the trader and the manufacturer. It was common for merchant princes, even down to recent times, to send their sons to the University to study the Humanities before their absorption into the whirl of business.

The triennial visit of a Lord Rector has always brought mercantile and academic Glasgow into close contact. Perhaps seldom did the citizens rouse themselves to such excitement as when Peel came to give his Rectorial address and 3,500 people banqueted to do him honour in a specially erected building; but we have heard from our fathers of the great scenes when Macaulay and Disraeli and Gladstone and Bright delivered the orations, and in our own day the citizens vied with students in receiving Chamberlain and Balfour and Asquith.

Progress since 1870.

When the University removed in 1870 there were twenty-five professors, one lecturer, and nine assistants, and the university buildings, arranged in two quadrangles, one side of the west quadrangle being left unfinished, were adequate. The last fifty years have seen a great expansion in all directions. In the past year there were forty-one professors, ninety-three lecturers, and fifty-three assistants, and the average numbers of students of the early years had vastly increased, till last session there were 3,574 men and 1,132 women. To meet the needs of all these thirsting for knowledge and keen to graduate, large thoroughly equipped laboratories have been added in physiology, anatomy, botany, chemistry, natural philosophy, surgery, engineering, materia medica, and forensic medicine. These lie mostly outside the main buildings, with certainly a rather serious disturbance of architectural symmetry. Plans are ready for the completion of the west side of the arts quadrangle, to provide much needed accommodation for the Arts Faculty, and to include a Chapel to be erected as a memorial to members of the University who fell in the war, while a large Natural History Department is at present under construction. Between the two quadrangles stands the Bute Hall, the gift of the late Marquis of Bute, an elegant structure in keeping with the general scheme of the whole. Within this hall the Representative Meeting and the large ceremonial meetings of the British Medical Association will be held in July. Adjoining it is the Randolph Hall, the gift of a Glasgow shipbuilder, to be used, we believe, as the temporary Council Room of the Association.

Queen Margaret College.

The women's department of the University has its academic home in Queen Margaret College, which has been altered from its old usage as a mansion house into classrooms and laboratories. This building is close to the Botanic Gardens, and is only a few minutes' walk from the University. The College was founded in 1883, and was the outcome in Scotland of the movement of the later sixties towards the higher education of women. It was therefore concomitant with the movement which resulted in the founding of Girton and Newnham. In 1892 Queen Margaret College became affiliated as the women's department of the University. Some of the classes are held in this College and others in Gilmorhill, while the clinical classes for women are conducted along with those for men in the three large infirmaries of the city.

Another affiliated college of great importance in an industrial city like Glasgow is the Royal Technical College, which is housed in perhaps the finest building of its kind in the country, situated near George Square, practically in the centre of the city. The Royal Technical College traces its origin to Anderson's University, founded in 1796, under the will of John Anderson, M.A., F.R.S., Professor of Natural Philosophy in the University. The Royal Technical College has had as members of its staff some of the foremost men of science of the day.

Hunterian Museum and the Library.

The Hunterian Museum and the Library are sources of praiseworthy pride to all Glasgow University men. William Hunter, disappointed with the Government's refusal to provide a School of Anatomy in London, in spite of his own offered munificence, told his friend Cullen that he had a "great inclination to do something considerable in Glasgow

some time or another." That something proved to be the bequeathing of his Museum to the University. The story of the Hunterian Museum is one of the most fascinating in the history of the University, and those who wish to pursue it will find ample reward in the pages of Mr. Cantt's *History of Glasgow University* and Dr. Mather's book, *Two Great Scotsmen—William and John Hunter*. It was the first of the great medical museums. But it was more. It was a magnificent collection of paintings, books, manuscripts, archaeological relics and coins. Numismatists place it among the greatest of the collections of coins and medals. When it was transferred to Glasgow in 1807 transport was a serious and costly business. The coins alone were brought by wagon in the care of six trusted, well-armed men, specially sent from Glasgow for the task.

The Library has been a University entity since 1475, and grows for many years more by gift than by purchase. Through many vicissitudes it has developed into one of the most substantial libraries in Scotland. There are now something like 203,000 volumes. The collection of ancient classical literature is of special value; no fewer than one hundred of the works were printed before 1500. The Ewing collection contains a first folio (1623) of Shakespeare. Among the treasures of the Library there is the MS. Psalter of 1172; various mediæval medical manuscripts; a series of fifteenth century manuscripts

of English prose and poetry, including the unique Chaucerian "Roman de la Rose" and Tardif's "Fauconnerie."

University Constitution.

The Constitution of all the Scottish universities is essentially the same, and perhaps English readers will appreciate a brief statement of the government of the University of Glasgow.

I. *The Chancellor* is the head of the University; he is elected by the General Council and holds office for life. The present Chancellor is the Earl of Rosebery, who easily maintains the honour held in past years by a Marquis of Hamilton, seven

Archbishops of Glasgow, four Dukes of Montrose, a Duke of Buccleuch, an Earl of Stair, and Lord Kelvin.

II. *The Vice-Chancellor* acts for the Chancellor in conferring degrees. Vice-General Council. The offices of Vice-Chancellor and General Council are usually merged.

III. *The University Court*. He holds office for three years and is elected by the students, who in their choice take account of his political colour first and his academic or scientific attainments next. Mr. Bonar Law at present holds the office. Our readers may remember that his Rectorial address was his last public effort before a serious breakdown in health. The next election is in November, 1922. The roll of Rectors bears the name of almost every statesman of outstanding eminence in the history of our country.

IV. *The Principal* is President of the Senate and a member of the University Court. He holds office for life, and the appointment is the gift of the Crown. Perhaps it is hardly necessary to state that the Principal is Sir Donald MacAlister, K.C.B., D.C.L., LL.D., President of the General Medical Council.

V. *The University Court* is the governing and directing body of the University. It consists of the Rector, the Principal, the Lord Provost of Glasgow, the Chancellor's assessor, the Town Council's assessor, four assessors elected by the General Council, and four by the Senate. It is obviously a body representing all interests in the City and in the University, wide in sympathy for all educational ends, watchful and skilled in material affairs.

VI. *The Senatus Academicus* consists of the Principal and Professors, and is concerned with the teaching and discipline.

VII. *The General Council* comprises the Chancellor, the Court, the Senate, and all Graduates; in the present year it consists of over 10,000 members. It meets twice a year, and, jointly with the other Scottish universities, elects three members of Parliament.

VIII. *The Students' Representative Council* consists of representatives, both men and women, from each faculty in the University, and its objective generally is the welfare and rights of the

Laidlaw, Glasgow.

student. The Scottish student has always been held up to admiration for his gifts of pertinacity and hard work. In former days he was poor and many a "lad o' pairts" found the meagre diet of porridge and a herring little enough to promote the high thinking urged upon him. "Meal Monday" is still a relic of these days. The student no longer goes home to replenish his "poke" of meal; he and his teachers gladly welcome these two holiday Mondays in February and March, the most strenuous part of the academic year. The Carnegie Trust now amply provides for the poor student, whose qualifications for receiving help from these funds are mainly two—that he must be a Scot and that his preliminary education must reach a certain moderate standard.

The present alumni of Glasgow possess a great heritage. The student who knows even a little of its history cannot but rejoice that he is a son of such a mother. If the names of Zachary Boyd, and Strang and Simpson and Stirling, leave him untouched, he may reflect that Adam Smith still is an influence in the world of economics, that Patrick Gillespie and Gilbert Burnet were statesmen principals and wielded influence in Courts. If he incline towards Natural Philosophy, he must become enthusiastic over James Watt and Black and Kelvin, three men whose discoveries marked new epochs in steam, in heat, in electricity. If he is a classicist, and not too young, he will tell you of the great days of Daniel Sandford, Richard C. Jebb, the Ramsays, and Edmund Law Lushington—Tonnyson's brother-in-law, immortalized in *In Memoriam*, "wearing all that weight of learning lightly like a flower." If he is now a middle-aged parson, he will tell you that there will never again be men like John and Edward Caird and Herbert Story, and John Nichol. While if the student belong to our own profession, his task of justifying his University is easy. Of the long list of distinguished professors in the Faculty of Medicine some stand out like the great peaks of the Grampians from amongst many great but lesser hills. William Jackson Hooker and Bayley Balfour in Botany, Andrew Buchanan both in Physic and in Surgery, Harry Rainey in Medicine, Easton in Materia Medica, MacKenzie in Ophthalmology, Jardine who did so much to found the Royal Infirmary, Allen Thomson and John Cleland in Anatomy, to select only a few, are to be classed amongst the Olympians. Nor would our student let his audience forget that surgery had its new birth when Lister was a Glasgow professor—all else he did later was simply to amplify the discoveries of 1861 to 1869; and when the name of William Tennant Gairdner is named, all that is highest and noblest and most lovable in medicine is transfigured before him in that great personality, which still dominates Glasgow medicine to-day.

Paris.

[FROM OUR CORRESPONDENT.]

THE FOREIGN POST-GRADUATE STUDENT IN FRANCE.

When one enters the old buildings of the Paris Faculty of Medicine it seems that nothing has changed since the now prehistoric period of before the war. The long lists of names, however, carved upon the wall and ending with the words "*Morts pour la France*," show that one is upon the threshold of new times. There is a new atmosphere in the old school, and its younger teachers have felt the necessity of leaving the serene attitudes of science and of living rather with their pupils, with the people, and with the world at large. It has been found necessary to link up the threads of French medicine with the web of foreign medical science—that is one of the lessons of the war.

At the entrance to the School of Medicine is an arrow pointing to the office of the "*Association des Développement des Relations Médicales*" (the Association for the Development of Medical Relations), more usually known by its initials as the "A.D.R.M." Its object is sufficiently expressed in its title; it was founded at the end of the war by a number of French physicians who were convinced of the necessity of such an organization in order that the links the war had forged with their allies and friends should not be broken. The association has as its honorary president the dean of the faculty, Professor Roger; Professor Hartmann is president; the section of propaganda is directed by Professor Vaquez, and representatives have been appointed to establish relations with the different foreign countries—for Great Britain, for instance, Dr. Gustave Monod has been appointed. The duties of the permanent secretary, Mlle. Hervé, include the pro-

mation he may require, aiding him from the day of his arrival in Paris, securing any introductions necessary for him, and of making him acquainted with the daily programme of the chief clinics. The work of the association at present is considerable, and is chiefly concerned with the organization in France of post-graduate teaching, which has become one of the chief questions of the day.

In addition to the ordinary courses, most of which are open to visitors, the Faculty of Medicine has organized a rotation of post-graduate courses, which allow the visiting medical man to become rapidly acquainted with the present situation of the subject he desires to study. Faithful to the traditions of the French school, all these courses are practical. Teaching is given actually at the bedside; the laboratory is used rather to stimulate the interest of the student than to demonstrate facts to him. In the case of foreign visitors the instruction is in the nature of collaboration or an exchange of ideas. These post-graduate courses are open to a limited number of students, and the fees vary from about two to four guineas. The courses of the Faculty of Medicine cover, it is hardly necessary to say, the entire field of medicine. More specifically of international character is the Institut Pasteur, where the work and the teaching has been again organized as it was before the war. The higher course in microbiology is open to medical men who have already attained a sufficient standard in laboratory work, and this course, which is of four months' duration, commences in January, 1922. To show the different directions in which research is open at the Institut it may be pointed out that its laboratories include those of cellular physiology, protozoology, biochemistry, pharmacology, physical chemistry, and serotherapy.

Outside the Faculty of Medicine the hospitals of Paris, with their inexhaustible scientific and clinical resources, offer hospitality to every visitor. It is well known that the hospitals of Paris are not, strictly speaking, medical schools; the instruction given in them is entirely clinical. Tradition has created certain centres of specialization: the Hospital of St. Louis, for instance, is the centre of dermatology, while the Salpêtrière and the Pitié, where Dr. Babinski teaches, form the centre for neurology. The medical teaching in the Paris hospitals, taken as a whole, provides a field of clinical study open to all visitors, and covering all specialties in medicine. These clinical demonstrations are all free. Although the A.D.R.M. has developed inside the Faculty of Medicine, it does not confine its activities within the walls of the Faculty. In Paris, as in London, an important school of post-graduate studies is being organized, and it may be hoped that this development may be as successful in the one capital as in the other.

A movement is on foot to enable all the regular medical students of the Paris schools to have the advantage of holding resident appointments in hospitals. It is clear that the present system of competitive examination tends to create a special class, and to encourage early specialization in medicine or in surgery. We may, perhaps, look forward to a time when during a student's last year there might be a special stage of night service, but the idea of resident appointments for all, which would involve a real levelling down, cannot be entertained; if it were allowed to undermine our great system of competitive examination, it could not fail to have undesirable results on professional recruiting. The conditions governing resident appointments have already been fundamentally improved by the institution of examinations on a more modern system, and, in particular, by a regulation which preserves the anonymity of a candidate in respect of written papers: this reform has long been demanded. The same equitable regulation is about to be applied to the competitive examination which qualifies the successful candidate to become a physician or surgeon of the Paris hospitals. This change—a revolution on a small scale—has been very quietly brought about.

Scotland.

RETIREMENT OF Dr. J. C. McVAIL.

A PRESENTATION has been made to Dr. J. C. McVail on the occasion of his retirement from the Scottish Board of Health, of which he has been a member since its institution, Sir George McCrae, chairman of the board, in making the presentation, referred to Dr. McVail's long and varied experience in the medical profession, first as a private practitioner, then as medical officer of health for the counties of Stirling and Dumfries, afterwards as one of the Scottish

National Health Insurance Commissioners, and latterly as a member of the Scottish Board of Health. In each of these capacities Dr. McVail had displayed exceptional abilities in discharging the difficult and onerous duties falling upon him. He had also been specially selected on several occasions to undertake inquiries on behalf of Government departments and Commissions. He had made a number of valuable contributions to medical literature, particularly in matters relating to public health. In reply, Dr. McVail referred to the changes which had taken place in medical science and practice since he first qualified, and particularly in regard to public health administration.

RED CROSS WAR WORK IN SCOTLAND.

On the recent occasion of the presentation at Glasgow to Sir George T. Beatson of his portrait, in recognition of his work as chairman from 1909 to 1920 of the council and executive committee of the Scottish Branch of the British Red Cross Society, Sir Alfred Keogh referred to the efforts which Sir George Beatson had made in building up the Red Cross organization which had stood Scotland in such good stead during the great war. It was important that the Red Cross should stick firmly to the principles then laid down and remain a voluntary body free from officialdom. In reply, Sir George Beatson reviewed the war work of the Scottish Red Cross Branch, which he considered had received too little general attention. A Central War Fund of over £2,000,000 was created, and over 600 motor ambulances, several motor ambulance launches and a naval hospital ship were provided. In addition to a 300-bed section of a military hospital at Rouen, 170 Red Cross hospitals were established all over Scotland; over 3,000 nursing members and 1,400 general service members of the V.A.D.'s did duty in the military hospitals. A never-failing supply of hospital comforts, surgical stores and dressings, and sphagnum moss was kept up throughout the campaign. The efficient organization outlasted every strain put upon it, and wonder had been expressed that a country with such a comparatively small population should have accomplished so much. The good work was being continued by the assistance given to the Ministry of Pensions hospitals at Ralston, Edenhall, Stornoway, and Warren Park. In acknowledging the gift of the portrait, Sir George Beatson said that he would always have a very happy recollection of the days when they laboured together for the Red Cross in Scotland.

THE PHYSIOLOGY OF BREATHING.

In the course of a lecture on the physiology of breathing, delivered in Edinburgh on December 24th in connexion with the mining department of the Heriot-Watt College, Dr. J. S. Haldane, of Oxford, referred to the kinetic theory of gases, which was first formulated by an Edinburgh man, James John Waterston. After a brilliant career at Edinburgh University Waterston became a civil engineer and went to India. In 1845 he sent to the Royal Society a now famous paper in which, long before anyone else, he clearly formulated the fundamental outlines of the kinetic theory of gases, one of the greatest scientific advances in the nineteenth century. The two Fellows who were appointed referees of his paper emphatically reported against the publication of the manuscript, but about ten years later the same theory was put forward by Clausius, the German physicist, and the new idea triumphed. Waterston, somewhat embittered, eventually retired from India to Edinburgh, and was believed to have been drowned off Leith pier in 1883, though his body was never found. Waterston's manuscript was ultimately discovered in the archives of the Royal Society by Lord Rayleigh, who published it in full in 1892, with an appreciative introduction. Discussing the regulation of the pressure of oxygen in the blood, Dr. Haldane said that evidence had accumulated recently that the pressure of oxygen in the blood in each part of the body was almost as exactly regulated as the pressure of carbonic acid gas. Great interest was at present being taken in the attempt to be made next summer to climb Mount Everest, and the physiological aspect of the ascent was of high scientific interest. If the climb to the summit at 29,000 feet should prove feasible that would be a result of extraordinary interest as showing the powers of adaptation in the human body.

REVIVALISM IN THE EAST OF SCOTLAND.

The newspapers have been for two or three weeks giving considerable space to the records of a wave of revivalism which has been sweeping over the East of Scotland and which

in the north-east of the country and which has more recently appeared in Eyemouth and Burnmouth in Berwickshire. The movement began apparently in Lowestoft where so many Scottish fishermen go in the fishing season, and it spread to Scotland with the return of these men after a season which had to be reckoned a failure. It is stated that revivals of a similar kind have followed previous seasons which were disastrous; but the present one has been accompanied by a greater degree of emotionalism on account of the coincident bad trade. At first fears were openly expressed that the psychology of the revival might pass over into the abnormal, and certainly the oratory was sometimes rather of the nature of a strong north-easter, and the results were somewhat startling and even fantastic. On the whole, however, the sturdy common sense of the fishermen has warded off dangers arising from over-stimulation of the emotions, and the probable result seems likely to be a real increase in the well-doing of the communities which have been affected, from Wick to Fraserburgh and from Peterhead to Eyemouth. It seems clear that the revival was absolutely unorganized and spontaneous in origin; but a little consideration will suffice to show that a fisherman's life of adventure and frequent desperate danger is one in which a vivid appreciation of the deepest feelings of which the human heart and mind are capable is likely to seek and to find outlet and expression in scenes and occurrences of high emotional character.

England and Wales.

WELSH NATIONAL SCHOOL OF MEDICINE.

SOME confusion has arisen in the public mind owing to the fact that two appeals for university education purposes in Wales were published, the one on December 6th and the other on December 7th. The Pro-Chancellor, Lord Kenyon, and the Vice-Chancellor, Professor A. H. Trow, have written to explain the situation. The two co-ordinate appeals, they say, were necessary, and indeed inevitable, and were issued with the approval of the University of Wales and the authorities of the University College of South Wales. "The Welsh National School of Medicine," they go on to state, "over its inception and its present position to the foresight and energy of the governing body of the University College of South Wales and Monmouthshire and their friends. When, however, the new charter of the University of Wales was granted, it became necessary to give a national and university status to the School of Medicine, although the administration remained in the hands of the Council of the University College of South Wales and Monmouthshire. Indeed, the Royal Commission recommended that the Medical School should be a separate constituent college. When, therefore, funds were required, it was the business of the University Council, as controlling the finances of all the university colleges in Wales, to issue the appeal on behalf of the Welsh National School of Medicine. The appeal of the University College of South Wales and Monmouthshire is entirely for its special and immediate needs, and is not in conflict with any other. The most urgent need of the college is for new laboratories in physics and chemistry, and these are as important for medical students as for students in pure science. Meanwhile, the need of the Welsh National School of Medicine for a fund of £100,000 (or its equivalent in annual income) before August, 1922, is very urgent in order that the school may qualify for the Treasury grant of £5,000 per annum. That grant is absolutely dependent on the success of the appeal, now made on behalf of the Welsh National School of Medicine, and contributions will be gladly acknowledged on behalf of the Appeal Committee by Mr. Gwilym Hughes, Organizing Secretary, Welsh National School of Medicine, Newport Road, Cardiff."

RED CROSS CLINICS.

At a general meeting of the Kensington Division of the British Medical Association held on December 19th, 1921, Dr. A. J. Rice-Oxley, C.B.E., Mayor of Kensington, made the following statement with regard to British Red Cross clinics:

"As many of you are aware, the Kensington Division of the British Red Cross has since the Armistice developed a clinic at 14, Prince of Wales Terrace, for the treatment of ex-service disabled men by massage, electricity, radiant heat, baths, and remedial exercises, and has established a

considerable equipment for this purpose. Now that the need of such treatment for ex-service men is rapidly diminishing, it seemed to the Executive Committee of the Kensington Division B.R.C.S. that it would be a pity to scrap this equipment, and that the clinic might be used to serve the needs of the general public, who, while in many cases able to contribute towards the cost of such treatment as the clinic provides, are unable to pay the whole cost. But the Executive Committee felt that it would be unwise to proceed with such a clinic without first consulting the local medical practitioners and establishing it on such a basis as would meet with the profession's approval. They therefore approached me with the request that I should endeavour to ascertain the views of the local medical practitioners. This I consented to do, and invitations were sent to some fifty medical men (time did not allow of a larger number of invitations, being sent) to meet me in the mayor's parlour to discuss the project. Some thirteen gentlemen attended the meeting and gave a provisional approval of the scheme. Further meetings have since been held for the purpose of elaborating the details of such a scheme, and a considerable measure of agreement with the Kensington Division B.R.C.S. has been obtained. The scheme provides for payment of graduated fees, recommendation by a doctor, engagement of a medical expert to supervise treatment, and the employment of an almoner, or the setting up of a committee to prevent use of the clinic by patients able to pay ordinary fees—that is, fees paid for such treatment in the locality. The scheme has been favourably considered by the County of London B.R.C.S. Executive Committee, and it is hoped that you will approve of and support such a clinic under proper safeguards for the medical profession, masseurs, and others at present engaged in administering this form of treatment."

CENTRAL MIDWIVES BOARD.

At a meeting of the Central Midwives Board for England and Wales, held on December 21st, 1921, with Sir Francis Champneys in the chair, four women were struck off the roll and two were cautioned.

A letter was read from the Medical Secretary of the Medical Women's Federation, forwarding the following resolution:

That the attention of the Medical Women's Federation having been drawn to the recent Order of the Minister of Health permitting midwives to carry opium, urges that this order be withdrawn in view of the dangers involved to the parturient woman and child. They would also point out that pituitrin is also being widely used, and similar restrictions should be exercised.

A resolution on the same subject, received from the Manchester City Council, was as follows:

That this subcommittee, being of opinion that it is a dangerous practice for midwives to carry and administer preparations containing opium, considers that such authority of the Secretary of State should be revoked, and that representations be made with that object to the Ministry of Health and the Central Midwives Board.

It was decided to forward to both bodies a copy of the resolution on the administration of drugs by midwives passed by the Board at its last meeting. The Board, in its reply to the British Medical Association (BRITISH MEDICAL JOURNAL, December 10th, 1921, p. 1005), stated that it had always declined to schedule drugs except so far as stated in Rule E 19; in its experience of nearly nineteen years it had never had a case before it in which a midwife had been found to have administered a drug improperly. Rule E 19 is as follows:

"A midwife must note in her register of cases each occasion on which she is under the necessity of administering or applying in any way any drug other than a simple aperient, the name and dose of the drug and the time and cause of its administration or application."

Ireland.

AMALGAMATION OF UNION HOSPITALS.

At a recent meeting of the committee of the County Galway medical practitioners evidence was taken from medical men in various parts of the county, with special reference to Connemara, as to how the present changes, arising out of amalgamation of workhouses, affect the health of the people. The following resolutions were passed:

1. That considering the vast area of the co. Galway and the appalling public health conditions throughout the Connemara country, we, the medical practitioners of the co. Galway, whilst agreeing generally with the principles of the amalgamation of Irish workhouses, strongly protest

against the wholesale abolition of the district hospitals as being inimical to both curative and preventive medicine; that we generally, in the past, experienced great trouble in getting the friends of patients, living at a distance from the district hospitals, to consent to their removal to the hospitals even when suffering from typhus and typhoid.

2. That we desire to remind the Dail Ministry of Local Government of the number of medical practitioners in the Connemara district who fell victims to typhus fever within the past twenty-five years; that this appalling medical mortality was almost entirely due to the conditions in which doctors were compelled to afford medical treatment to the fever-stricken patients in the insanitary hovels, and that the abolition of the district hospitals will make matters in those respects very much worse in the future.
3. That the Dail Government should at once appoint a medical commissioner to inquire specially with regard to the public health conditions in Connemara.
4. That we view with much disappointment and disapproval the failure of the County Health Boards to avail themselves of the services of existing medical officials when making appointments under the reformed medical schemes, particularly as it frequently happens that the reappointment of such officers would be in the best interests of the sick.
5. That we are unanimously of opinion that the medical provisions of the present amalgamation scheme should be suspended until a commission, on which the medical profession would be adequately represented, would formulate a scheme for an efficient Irish medical service suitable to the requirements of the country.

Dr. T. Hennessy, Irish Medical Secretary, attended the meeting on invitation.

THE TYRONE COUNTY HOSPITAL.

Dr. Edward Thompson, F.R.C.S.I., surgeon to the Tyrone County Hospital, in his annual report to the Joint Committee of Management, expresses his regret that the cost of the hospital continues to increase, owing to the increased cost of food, coal, and labour, as is the common fate of all hospitals here and elsewhere. There has also been an increase in the number of patients in recent years, which is due, to some extent, to the closing of several of the district hospitals.

We are constantly experiencing criticism (he continues) because of the report that the hospital is said not to be of much use to certain outlying districts of Tyrone, such as Dungannon and Cookstown. I have over and over again refuted those statements, and shown that a great many cases requiring surgical treatment find their way to this hospital from the districts in question. . . . The hospital is as freely open to them as it is to all the other districts of Tyrone, and if it serves the latter faithfully and well (as those reports show) it should be equally of use to all parts of the county. . . . One thing I am certain of, you have in Tyrone an excellent and up-to-date hospital, and, although it costs a good deal in these days to keep it up to date, there is not one penny spent which can be avoided.

To show that it is well appreciated, it is only necessary to intimate that since I was appointed in April, 1875, the number of internal patients has risen from about 500 to nearly 900, and the number of operations from 60 to close upon 300, and sometimes in excess of this figure. Another point of importance: the hospital is able to make a private income of £3,000 per annum, therefore the County Council gets for an annual grant of £3,000 per annum £6,000 in value. Not a bad bargain! Personally, I am tired of having to repeat those and other arguments in favour of the hospital.

Now, as always in the past, Miss Hayes, Mr. M. Adam, the sisters, nurses, and servants render me the most efficient service, and although the hours of their daily duty are long, I never hear any complaint; on the contrary, always willing and devoted service, at all hours of the day and night. I have also received the greatest help from Dr. O'Doherty and Dr. Lagan, and to them also I tender my most grateful thanks.

During the year with which the report deals there were 243 major operations and 527 minor operations performed in the County Hospital. The major operations included 34 amputations, 1 gastro-enterostomy, 22 for the radical cure of hernia, 1 prostatectomy, 2 for ventral fixation of uterine, 4 for removal of bullets, and 3 for removal of ovarian tumours.

THE seventh centenary of the University of Padua will be celebrated next spring. The executive committee consists of Professor Lucatello as president and two professors of each faculty.

At a recent congress of medical Esperantists at Prague Professors Gariel and Richet of Paris were elected presidents of honour, Dr. Vanverts of Lille president, Dr. Ansterlitz of Czechoslovakia secretary, and Dr. Cass of London treasurer.

BEHRING'S Institute, founded at Marburg in 1875, has been given the title of Institute of Experimental Therapeutics, like that founded by Ehrlich at Frankfurt. It is to be under the direction of Professor Uhlenhuth, formerly of Strasbourg.

Correspondence.

HOSPITAL POLICY.

SIR,—In his letter published in the JOURNAL of December 14 (p. 1095) the Chairman of the Hospitals Committee announces with due pomp and circumstance, and in tones free from all traces of tremor, the precise meaning of the term "voluntary hospital." Presumably, therefore, the art of authoritative definition is included in the list of responsibilities undertaken either by the Chairman or by his Committee, and it may gently be suggested that in the present instance no prerogative is exercised in a somewhat arbitrary fashion. For, while the definition is imposed as from above, neither rhyme nor reason is advanced in its support. In these circumstances I venture to ask myself, is the voice really that of the Hospitals Committee or is it just possible that Mr. Harman himself is the power behind the Chairman's throne? The question is not unimportant. In the one case we have to deal with an organ of the Association; in the other, with an individual who has on our regard many claims outside the area within which are fixed the origin, history, and meaning of words.

Whatever be the exact authenticity, there is now proclaimed the plain proposition that, given only "voluntary and independent management," a hospital is "voluntary" even though it is supported solely by payments received from patients, and even though the medical officers, no longer honorary, receive fees for their professional services. There may be contributions from the charitable public; there may be doctors rendering honorary services. But such factors, when they exist, are mere accidents or non-essentials; they complicate and perplex a situation which finds its essential expression in "voluntary and independent management" unassociated either with voluntary contributions or with honorary services. The "sole test" is gratuitous management; all else is superfluous and unnecessary. Perhaps to the curious it may occur to ask, Where may be found the hospitals that thus show the "voluntary" principle in its true, simple, and uncomplicated expression? On the terms of the definition, municipal hospitals for, say, the reception of cases of infectious disease would appear to fall within it. But this is denied. Indeed, the sharpest possible contrast is drawn between "voluntary and independent" managers and the "representatives of the ratepayers." There may perchance be some stirring in the municipal dockets when worthy aldermen and councillors are told that their services are not voluntary and that their actions are not independent. But such a conclusion is inevitable once the Hospitals Committee's propositions are granted.

As opposed to the arbitrary definition offered to us I suggest that the history of the term "voluntary hospitals" and the actual working of the hospitals demand an entirely different reading from that announced in so imperious a tone. These institutions have rested their claim to public interest and help largely on the statement that they are "supported by voluntary contributions," and not a few of them continue to recite this formula. By a loose habit of speaking and writing, and with a natural desire for brevity, the term "voluntary" has commonly been extended from the "contributions" to the "hospitals," where, strictly speaking, it is incapable of defence, though justified, or at least excused, on the ground of convenience. And most certainly the voluntary system as it has existed until the present day has implied contributions in cash or kind given voluntarily, and services, administrative and professional, rendered gratuitously. Such is, in fact, the centre or heart of the hospital organization and activities of which Great Britain has justly been proud.

Now comes the Chairman of the Hospitals Committee to announce *ex cathedra* that gratuitous contributions, whether of money or of service, are non-essential and unnecessary, and that their disappearance will leave the "voluntary hospital" in its pure and undiluted essence to continue an undiminished existence. Patients may pay for their maintenance and treatment and doctors may pocket their share of the payments. But, given only "voluntary and independent management," all this is immaterial. The "voluntary hospital," reduced to its essential principle, will then be seen in its true glory, but for what period of time the "voluntary and independent management" will endure in such circumstances is left to conjecture. (The British Medical

Journal, 1921, p. 1095.) It would be well to know whether such a desire is limited to the attenuated form presented by the Chairman of the Hospitals Committee.—I am, etc.,
London, W., Dec. 27th, 1921. C. O. HAWTHORNE.

SIR,—I hasten to thank Mr. Harman for his courteous remarks upon my letter, and his laboured definition of the status of voluntary hospitals. I must, however, remind him that the fate of the Leicester motion, which is the subject of the letter, will be decided by the lay committees of these institutions, who are likely to attach more importance to the opinion of the Cave Committee, backed by the staffs of Scottish hospitals, which seem to be better managed financially than our own, and supplemented now by a large fraction of the staffs of those in London, than to the opinion of Mr. Harman, backed though he may be by the Representative Body. Now the Cave Committee, in the very passage quoted, has defined quite plainly the limits which must not be exceeded if the safety of voluntary hospitals is to be preserved, and it is transparently clear that, while my amendment and that of the Scottish hospitals lie well within these limits, the Leicester motion most seriously transgresses them, and is, therefore, a direct menace to the voluntary system. How Mr. Harman can dismiss, in the airy way he does, so weighty an indictment, delivered by the Cave Committee after twenty years, is unintelligible to me as his reason for so pronouncing it mild when quoted by him, it as falsely emphatic and "in striking contrast to itself when quoted by me, without emphasis, comment, or addition. Now at the Representative Meeting the Chairman of the Council apparently regarded this judgement of the Cave Committee as so serious that he moved a formal protest against it. I must leave the Chairman of the Hospitals Committee to explain his casual attitude towards the same matter to the Chairman of the Council. Mr. Harman's reference to the two distinguished physicians is quite inappropriate. They and most others receive payment for treating certain patients, but this is no reason why all should levy toll on every pittance paid for maintenance, which is no part of the duty of the staff. Mr. Harman appears to be unable to perceive the fundamental difference between treatment and maintenance. It is, however, very clear to the staffs of Scottish hospitals, it is becoming increasingly clear to staffs in London, and is certainly not overlooked by any lay committee in London or the provinces. Its recognition will infallibly wreck the Leicester motion, despite any efforts of Mr. Harman to bolster it up. I will not waste space by answering his strictures on my brief summaries of the proceedings at the Conference and Representative Meeting. I have given the references to the reports of both, and readers can form their own opinion as to who is "distorting facts."

With one dictum of Mr. Harman I find myself in complete accord. An innovation so drastic and revolutionary as the Leicester motion certainly craves much calm deliberation—a great deal more than it has yet received. I would add that, as it vitally endangers the maintenance of hospitals, it is futile and indeed absurd to come to any formal decision upon it without consulting the laity, by whom hospitals are in fact maintained.—I am, etc.,

Chichester, Dec. 24th, 1921.

G. C. GARRATT.

HOSPITALS IN THE TERRITORIAL FORCE.

SIR,—Your correspondent, "Late Capt. à la suite," has done wisely in hiding his identity, as his letter (December 24th, 1921, p. 1095) is a severe indictment of the way in which his O.C. administered the hospital under his charge. That a reformed system is necessary for military home hospitals is evident, but whatever changes there are will not be on the lines your correspondent suggests. He does not seem to appreciate that in dealing with soldiers there are many things which have to be taken into consideration that do not apply to civilian patients, and he gives no credit to the intelligence of the many able minds which have evolved the present military system of hospital administration and organization.

He tells us that he considers the system in vogue antiquated, and suggests as an alternative to administer it on a democratic basis. This latter has not yet been tried in a civil hospital, but it might be attempted there to see how it would work. Civilian hospitals are run by a lay

committee, and the honorary staff only have a very small representation. If he is consistent in his proposal, he must be thoroughly democratic and there should be proportional representation of all concerned; the staff, nurses, orderlies, and patients in their due proportion must have vote in the administration. There must be no bureaucratic control by a small privileged class of highly qualified doctors. The meeting must be open to the public—no Star Chamber inquiries—or we shall have letters in the public press and comments by "Our Medical Correspondent."

The most revealing thing about "late Capt.'s" letter is that he has evidently not taken the trouble in the five years he served to understand the army medical system. He certainly has not learnt the first lesson of a soldier—namely, obedience. Had he studied the T.F. Regulations he would have found that the medical man put in charge of a general hospital is in possession of the King's commission, and does a yearly training in a military hospital. He does not "arrogate to" himself the position of a commanding officer, as he is appointed to that rank with the duty of carrying out the functions of that position. Neither does "late Capt." appear to have read the Regulations of the Army Medical Service (price 4d.); had he done so he would have found that his "gaps" do not exist.

He then castigates his O.C. (perhaps unintentionally) by saying that he had to sign "hundreds of letters and forms" when he was orderly officer. It must have been a very busy hospital to have so much daily correspondence, and I think "late Capt." has overstated the numbers. Why the O.C. or the registrar so neglected their work is not told us. For my own part I cannot see why the clerical work of making formal replies and filling up forms cannot be done by the sergeant-major, or "even a less highly placed N.C.O." Does "late Capt." wish to do it himself? My experience was that they did their clerical work very well, and that after a short instruction female clerks could be trusted with much routine work.

Your correspondent falls foul of the D.D.M.S. because he would not speak to the orderly officer (though a physician on the staff of a great civil hospital of the town and a man of the highest professional status) as he was not of field rank. What a scandalous thing! I suppose "late Capt." knows what the D.D.M.S. wanted to say to the O.C., and that it was a matter fit for the ears of a man of the highest professional status. Otherwise there is nothing in it. Personally, when I want to communicate with a certain person on the telephone I like to speak to him himself and do not care to be put off with physicians of high professional status, much as I respect them. And yet I have held resident posts in a civil hospital, and have been a physician on a hospital staff!

But to return to a more serious line of thought. The *à la suite* hospitals have not come up to the expectations that were formed of them and a new system is necessary. I need not say why or how they failed. Anyone who was in charge of a hospital during the war and kept his ears and eyes open knows why. But I may tell "late Capt." this, that the efficiency of a military hospital, whether a general, a war or a purely military hospital, depends on the O.C. The system is the best yet devised for soldiers and the well-being of the patients; the efficiency of the administration and the comfort of the officers depends entirely on the qualities of the officer commanding and on him alone. Given a good O.C. all will go well, but with an inefficient one there will exist the "friction and ill-feeling" that "late Capt." tells us was such a prominent feature of the hospital he served in.

Having criticized "late Capt.'s" letter pretty freely, I must in duty bound say I agree with him in two matters. He says "the duty of a subordinate officer is not to suggest but to obey." He has got this into his head but not his heart. The other matter is the question of recognition for our services in the home hospitals. I am glad to see that the South African Government sent us their warm appreciation of our services. Beyond a printed letter from the Army Council this is all we have to show for our arduous and lengthy service during the greatest war the world has ever seen and in which we came off victors. One would have thought that a little more generous appreciation might have been awarded us. It was due to no fault of many of us that we could not serve overseas; but at least we did our duty as far as circumstances, our age, and our physical disabilities allowed us. Some of us had even taken the trouble to become efficient in our own "conditions of service" before the war.—I am, etc.,

BERTRAM M. H. ROGERS.

Bristol, Dec. 25th, 1921.

TREATMENT OF CARCINOMA OF THE CERVIX.

SIR.—In your issue of December 31st appear two papers, by Dr. Fletcher Shaw and by Dr. Victor Bonney, on the treatment of cancer of the cervix, in which the extended abdominal hysterectomy is mainly dealt with.

Dr. Fletcher Shaw says of vaginal hysterectomy, "it was only in rare cases that the patient after vaginal hysterectomy did not have fairly early recurrence of the growth, and that is what would be expected." The danger of local implantation, to which he alludes, can be largely avoided by the use of the canter knife or by dissecting up and closing a cuff of the vagina before removing the uterus. Dr. Shaw's statement that "early recurrence was almost inevitable" may be true in those clinics where "the malignant mass was rubbed into the raw wound," but it is not borne out by the facts observed at other clinics.

Of 25 cases (up to the year 1901) operated on by me by the vagina, almost all with the canter knife, all recovered from the operation and 6 were alive and well from six to twenty-five years after the operation. Possibly more than 6 were cured, for in 3 cases the after-history could not be obtained.

Of 211 cases operated on by Schauta by the extended vaginal operation 73, or 34.5 per cent., were alive and well after five years. Schauta's results, as to cure, were practically the same as Wertheim's.

Comparing the results of the two chief exponents of the two operations—

	Mor-	Opera-	Absolute
	tality.	bility.	cure.
Schauta (extended vaginal hysterectomy)	7.5	51.3	18.4 (21.9)
Wertheim (" abdominal ")	18.6	50	18.3

It is seen that to obtain virtually the same result Wertheim sacrificed 11 patients to the severer operation.

Dr. Shaw's mortality rate for the extended abdominal hysterectomy was 19 per cent., Dr. Bonney's 20 per cent. This is a very high death rate; but it is about the same as that of those who have had most experience of the operation. Thus, Bumm's was 21, Wertheim's 18.6, Döderlein's 18.1, Krönig's 25.42, Franqué and Langhans's 19.8, Hofmeier's 20, Franz's 15.2, Zweifel's 14.

Wertheim's later lower mortality was admittedly due to his operating on less advanced cases than formerly. Amongst Dr. Bonney's 20 deaths 11 occurred in patients in whom the glands were not carcinomatous. It is probable that 10 of these patients would have survived vaginal hysterectomy and that 2 of them would have been cured and thereby have improved Dr. Bonney's excellent results.

The object of this letter is to plead for the exercise of judgement in the operation to be performed. The extended abdominal hysterectomy, for which Dr. Shaw and Dr. Bonney have the enthusiasm of somewhat late converts, undoubtedly enables cases of cancer of the cervix to be cured which are not curable by the vagina; the vaginal operation enables patients who are fat, feeble, or advanced in years to survive and to be cured when they would succumb to the extended abdominal operation. Cases of early squamous carcinoma of the portio can be cured by high amputation or vaginal hysterectomy with the cautery without, in my experience, any risk of death.

Our great need is to get the cases early, so that the dangerous operation, extended abdominal hysterectomy, may be avoided.

Till recently we have not had sufficient radium at University College Hospital to use it extensively. Now that we have a large supply I hope much from high amputation and vaginal hysterectomy, followed by radium and x rays, and from Recasens's method of applying small doses of radium at ten day intervals. I have performed the extended abdominal hysterectomy ten days after the application of radium, and think with Dr. Shaw that this is worthy of trial, as it does not materially increase the difficulty of the operation.

Meanwhile, let us not overlook the world's evidence of the last thirty years, nor await the English evidence of the next seven. Let those with opportunities use radium and x rays in combination with operation. Let us hope that Wertheim's feeling, to which he gave utterance not long before his lamented death, that radium would probably render all his former labours in vain, will prove true. Of the efficacy of radium in cancer of the cervix there is abundant evidence from foreign clinics; let us study the best methods of its use. Of this operation of all others it may be said:

Fas est et ab hoste doceri.

—I am, etc.,

London, W., Jan. 1st.

HERBERT R. SIENGER.

SIR,—I have read Dr. Fletcher Shaw's paper on "The present position of the treatment of carcinoma of the cervix" with much interest. Whilst appreciating the compliment Dr. Fletcher Shaw pays to Mr. Victor Bonney and myself in alluding to our work on carcinoma of the cervix, I think when writing a paper with such an important title he really should have taken the trouble to ascertain whether any later figures of ours than those he quotes were available. The reference giving our operability rate as 67 per cent. is taken from the first edition of our *Gynaecological Surgery*, and refers to patients operated upon between 1900 and 1903, that is twelve years ago, whilst the reference he quoted second-hand from Professor T. Wilson's article allude to work he published in 1913, nearly nine years ago. As Dr. Fletcher Shaw presumably went carefully into the subject, it is surprising that he is unaware that in 1916 Mr. Victor Bonney and I published in the *BRITISH MEDICAL JOURNAL* a series of 100 radical operations for carcinoma of the cervix, based on a five years' freedom from recurrence, the first that had appeared in this country. Again in 1920 the same figures are set out at length in the second edition of the *Gynaecological Surgery*. The old figures that Dr. Fletcher Shaw quotes in his paper, so far as our practice and results are concerned, give an entirely erroneous impression of the present position of the treatment of carcinoma of the cervix, and it is indeed fortunate that Mr. Victor Bonney's paper appears in the same issue, which will enable your readers to make the necessary corrections.

Figures dealing with the radical operation are of no value unless they include a considerable series of cases which are founded on a three years' freedom from recurrence with reference to the life-prolonging effects of the operation, or on a five years' freedom from recurrence, constituting an "absolute cure" (though Mr. Victor Bonney's paper shows that seven years are really required to make such a claim). In this country myself and I are the only surgeons who have published such figures, and I think it is most desirable that others practising this operation should defer publishing their results until they can produce a similar series of cases, as only by such can the real value of the operation be determined.

It may interest Dr. Fletcher Shaw to know that in 1913 we first performed the radical operation on an "inoperable case" made "operable" by radium, the patient being sent to us from the Radium Institute in London. Since then we have from time to time had opportunities of repeating such an operation, and our experience coincides with his, that the dense fibrosis produced by the previous application of radium makes the procedure extremely difficult.—I am, etc.,

London, W., Jan. 2nd.

CONYNS BERKELEY.

PEPTIC JEJUNAL ULCER.

SIR,—Your interesting reference to this lesion in an annotation published on December 24th, 1921 (p. 1092) will, I dare say, reawaken in the minds of some, as it has done in mine, the very cogent question: To what extent is the surgical technique of gastro-jejunostomy to blame for the formation of peptic jejunal ulcers? That the lesion may be the direct result of some defect in the method of operating is, I believe, generally accepted; and the more likely is this view to be correct when not only pathologists, but surgeons themselves are willing to acknowledge its probability. Thus, Dr. Georges Loewy, of the surgical clinic of the Salpêtrière, as quoted by you, gives as the first of the three possible causes for the formation of these ulcers, "errors in surgical technique." It has been pointed out that these ulcers may be classified into two sets, those occurring at the line of union of the bowel to the stomach and those limited strictly to the jejunum, that is, distal to the line of suture. It is only with the former that the question of a purely operative cause can be entertained.

Apart altogether from the preventable "errors" committed by inexperienced or careless operators, are there any defects in the details of recognized efficient methods likely to conduce to the formation of these post-operative ulcers? As far as I know, there are only two primarily essential methods of accurately uniting together the cut edges of the stomach and the jejunum to form the fistula *bi-mucosa*—and, of course, it is assumed that every experienced operator does accurately unite these edges—the one is by the use of a clamp devised specially for the purpose, and the other by simple suture without the aid of clamps. As a matter of operative convenience, and as a means of execution with greater

rapidity, the use of clamps is a distinct advantage but this advantage is possibly considerably outweighed by the effect which the clamping of the tissues has in interfering with the proper supply of blood to the edges of the artificial opening; it is more than likely that the clamping of the visceral walls during the process of suturing causes the small vessels passing to the wound edges to become thrombosed, so that the resulting delay in greatly needed rapid repair leaves a weak line of defence against the powerful digestive action of the gastric secretion. It is on similar grounds of interfering as little as possible with the supply of blood to the cut edges that—without the aid of clamps—the too vigorous and multiple employment of forcepressure forceps to bleeding points may crush and devitalize tissues to such an extent that they may be just as easily digested by the gastric juices. It has been in order to avoid these possible devitalizing influences upon the line of suture that, in my own practice, I have always sought to ligature as few vessels as possible along the wound edges, using a continuous suture of absorbable material that embraced all coats of the stomach and bowel, and therefore, at the same time, occluding any bleeding points.

Whether I am right in concluding that the use of clamps may, in the way indicated, be a cause of the formation of that particular class of ulcer occasionally found at the line of suture, could be easily proved if it were possible to ascertain, in any case of the kind that occurred, whether clamps were used at the operation of gastro-jejunostomy. When it is remembered that the existence of these ulcers is usually only made known to us by sudden perforation, and therefore that the case may fall into another hand than that which originally performed the operation, statistics of any practicable value become very difficult, if not impossible, to obtain. We are more or less compelled, therefore, to act on purely theoretical considerations, based, however, on grounds that are both pathologically and surgically reasonable.—I am, etc.,

Glasgow, Dec. 23rd 1921.

A. ERNEST MAYLARD.

TREATMENT OF ACUTE GONORRHOEA BY ELECTROLYSIS.

SIR,—Without entering into the merits or otherwise of the treatment of acute gonorrhoea by electrolysis I should like to offer a criticism of Mr. Russ's article in the *BRITISH MEDICAL JOURNAL* for December 31st, 1921.

In the first place he appears to revive the ancient pathology that the gonorrhoeal process as it occurs in the urethra is accompanied by ulceration, and that this is the basis of stricture. It is true, he says, that "probably the use of strong caustic chemicals, either as bougies or as instillations, produces the initial chemical lesion which initiates the ulcer formation."

The urethroscope knows quite well that ulceration, as ordinarily understood, is a pathological curiosity in gonorrhoeal inflammation of the urethral mucous membrane, caustics or no caustics. The process is a thickening one and not a destructive one. The deposit of young cells called forth by the irritation is Nature's proper response to limit the affection, but in the case of a tube like the urethra the final result may be disastrous, owing to the contraction of the deposit. Nature is more concerned with the immediate arrest of the infection than the final result to the individual.

The superficial thickened layers of epithelium which cover the masses of young cells—the precursors of stricture—necrose and are cast off, but the process does not denude and necrose the subepithelial tissue to form an open ulcer. Correct conception of the pathology will lead to treatment directed to expand the canal and so bring about absorption of the young deposit before its conversion into hard and contracting fibrous tissue (stricture).

The statement that in the series of 500 cases no stricture occurred is not very convincing. Presumably the clinical signs of stricture is meant, as no indication is given that an examination of the canal was made for commencing stricture. It takes many years in most cases for the urethra to be so narrowed by stricture as to give clinical evidence of its presence; when this happens the time for cure is passed. It is indeed difficult to believe that of 213 cases of chronic gonorrhoea which were treated, not one of less than two months' duration, some did not require dilatation treatment. It would be quite contrary to my experience.

Again, with regard to immunity from arthritis and fascial complications in his series of cases, I may say that during

the war period I treated in private a very large number of cases of gonorrhoea—I was doing the work of three or four absent specialists besides my own—chiefly by the irrigation method, with, in chronic cases, dilatations and cauterization of lacunae, and I cannot recall one case of arthritis or any sort of joint rheumatism. A little muscular or fascial rheumatism is always with us, and one cannot usually tell whether it is due to the gonococcus or not.

Not a word is said about the spread of the disease to the posterior urethra and its treatment. It is stated that epididymitis occurs occasionally, which is proof of the extension of the infection to the prostatic urethra. Now, in first attacks the disease spreads to the posterior urethra in 70 or 80 per cent. of cases under expectant treatment. Is it held that this treatment of the anterior urethra—for this is what we are led to believe—is so successful that the extension to the deep urethra and prostate is so rare that it is not worth mentioning?

I may here draw attention to a very important point in dealing with statistics as to the rapidity of cure of gonorrhoea. It is that if first attacks are excluded the average time it takes to cure by the irrigation method (with possibly dilatations and treatment of lacunae by probe and caustic) is one week or, at the outside, ten days, if treatment is commenced early. The tendency to spread to the posterior urethra is much less than in first infections. Not at all infrequently when a man comes suffering from a third or fourth attack one voluminous irrigation with potassium permanganate will dispose of the disease, and it does not matter whether he comes on the first day of the discharge or not. I am not including those deceptive cases of relapse which only apparently clear up with one irrigation.

The urethral mucous membrane becomes profoundly altered after successive attacks of inflammation or after one long attack. It not only thickens and whitens as seen with the aëro urethroscope, but the columnar epithelium is replaced by several layers of flattened cells, and although the bactericidal qualities of these cells are lost in secondary infections it forms an unfavourable soil for the growth of the gonococcus.—I am, etc.,

London, W., Jan. 1st.

W. WYNDHAM POWELL, F.R.C.S.

VENEREAL CLINICS: A LAY POINT OF VIEW.

SIR,—The remarkable letter of "Venerealee" in a recent number of the JOURNAL—remarkable as evidence of a callous egoism and total lack of honourable principles—has been dealt with by several of your correspondents, mostly from the moral standpoint. There is yet a point which has not received sufficient notice—namely, what right have "Venerealee" and his kind to expect free treatment for diseases contracted through wilful exposure to infections of the consequences of which they are fully aware? "Venerealee" sings the praises of the venereal clinics; I may remind him that these were originally intended for those unable to pay for special treatment, although I have it on the best authority that they are shamefully abused by hundreds who can well afford to pay.

"Venerealee" and his congeners think nothing of sacrificing much gold at the shrine of Venus and view the consequences with indifference; for, as they no doubt remark, "hang the expense, we can always be cured for nothing!" Is it not monstrous that the ratepayers should have to contribute towards the maintenance of these "sexual heroes"?—I am, etc.,

London, W., Jan. 2nd.

C. F. MARSHALL.

SIR,—Mr. Wansey Baily and Captain Armstrong have I fear, "jumped at conclusions" in commenting on the attitude of women, especially of medical women, towards the wide incidence of sexual irregularities in men. It is no doubt trying for them, when they wish us to think the world such a very bad place, that we do not hasten to support them.

A great deal of the work of medical women is concerned with the habits and relations of the sexes, they are women of the world, and know quite as much about these things as their men colleagues.

Medical women will certainly not agree with Captain Armstrong's estimates and figures. They would probably reply that, to their certain knowledge there are a large number of men and boys who have lived, and are living, controlled and continent lives because they believe it to be their duty, and that they all know of exceedingly happy marriages that have followed such living.

While women have never been drawn to bloodless "plaster image saints," they are not attracted to the weak and infantile form of sexuality which is satisfied by casual intercourse or temporary unions. The life of sex, in its fullness, has no relation at all to prostitution of this kind. Women are most attracted to men who are whole men, and who will do and suffer something to attain to full manhood, and to an adult and virile sexuality and point of view.

Morality is the crystallized experience of the race painfully evolved through countless centuries. The moral beliefs of a community are shown by its laws and customs. Our people have at any rate worked out the simple beliefs that every individual has a power of free choice which governs the expression of his instincts, that man is man, and master of his fate, that he is the final director of himself, and that he is responsible to the community he lives in for his acts and their consequences. There appears to be no upholders of the opposite point of view, and even those who fall to the "double standard" take care not to proclaim their own misdeeds and diseases in public.

As regards "notification," "self-disinfection," or any other royal road or universal or quack remedy, "in vain is their net spread in the sight of" any thinking woman. Women want a world that is fit to live in, and has in it a great many more of the whole, responsible, adult men and women who are fit to trust and to marry. These are the people whom we think it of value to our race to uphold and encourage. We refuse to call ours an idle dream.

Mr. Wansey Baily and Captain Armstrong "can have" "Venerealee" and all his tribe if they care to waste good time on them.—I am, etc.,

East Grinstead, Jan. 1st.

MARY GORDON.

This discussion has now travelled far beyond the subject of venereal clinics, and the correspondence may properly close with Dr. Mary Gordon's statement of the medical woman's point of view.

POST-GRADUATE COURSES IN VIENNA.

SIR,—It is a great pleasure to me to send you information you were kind enough to ask as to the post-graduate courses of the medical faculty in Vienna. They were well known before the war, and are rapidly regaining their pre-war reputation. In our present conditions there are many difficulties to be overcome; in many respects things are different from before, but this gives us the opportunity of finding out new ways and new methods of post-graduate teaching.

There is an organization for medical post-graduate instruction at the University of Vienna, under the supervision of the medical faculty. The secretary, to whom all correspondence should be addressed, is Dr. A. Kronfeld, Wien IX, Fergellangasse 22. Different courses will be given.

The following programme has been arranged for next year:

1. Two weeks' international courses, consisting of single lectures during the whole time, given by workers on the special problems of the subject. The courses will be held four times a year. In September a course for country practitioners will be given every year. During these courses an hour in the morning will be kept free for demonstrations and for asking questions. The courses are free, a small contribution for necessary expenses only having to be paid. During 1921 four such fortnightly courses were held, and proved a great success; one was on internal medicine and neurology, and others on surgery, obstetrics, gynaecology and orthopaedics, oto-laryngology, urology, ophthalmology, dermatology, and venereal diseases; there was also one for country doctors mainly on the borderland of internal medicine and surgery. The next course will start on February 5th, 1922, on diseases of stomach, bowels, pancreas, liver, and spleen.

2. During the whole year special courses will be given, for which quarterly programmes will be issued. Most of these courses are paid for. The fee is stated in the programme. As a rule it is lower than the pre-war fee; the big figures are a sign of the unfair financial conditions under which we are living, one pound sterling being equal to 25,000 Austrian kronen or more. The programme may be had from the secretary above mentioned. I take leave to send a number of them to the office of the British Medical Journal. Special private courses and courses in the English language may be arranged on application.

3. A scheme will be worked out for clinical demonstrations in various clinics. As an attempt in this direction the senior staff of my clinic (medical) and I myself will have the pleasure of demonstrating specially interesting cases on every

Friday at noon, beginning on Friday, January 20th, 1922. These demonstrations will be open to doctors from all nations.

The old "American Medical Association of Vienna" is rising from its ashes, and will be reorganized in the near future. It is trying to find club rooms. English-speaking doctors have always been accepted as temporary members of this association, so that they would find the English accommodation and conversation. It is of great importance that visitors should have sufficient knowledge of the German language; we are still a German university, and as visitors are coming from many parts of the world general courses will, of course, be given in the German language.

The secretary of the organization will give information about residence, cost of living, etc. Although prices are running up madly (in kronen) visitors coming with a good currency will be able to live here cheaper than in any other part of the world.

Visitors of all nations will find a hearty welcome in Vienna. The only guarantee for a friendly intercourse is that the medical faculty require the signing of a declaration that our guest disapproves of the exclusion of German-speaking doctors from international congresses.—I am, etc.,

K. P. WENCKEBACH,

Director of the Institute of Medicine and Professor of Medical Pathology and Therapeutics.

Vienna, Dec. 23rd, 1921.

A copy of the programme, so long as the stock lasts, will be forwarded to inquirers on receipt of postage.

BREAST CANCER.

SIR,—The skill and care shown by your reviewer in abstracting some of the main features of my recent publications make me more sorry a statement of mine had misled him.

Important as the notion may be, I did not postulate the theory that the secretion of cancer cells could induce other cells to multiply. In the sentence that possibly misled him I endeavoured to indicate a line of study into which I had not entered—namely the examination of those changes which occur within an epithelial cell when its multiplication is induced by the stimulus of irritation. There is one observation to which he did not allude—that is there are two kinds of duct cancer, the papilliform and the laciform.

In making these statements I hope your reviewer will not consider me ungracious. I thank him very much for stating so clearly my case.—I am, etc.,

London, W., Dec. 26th, 1921.

G. LENTHAL CHEATLE.

THE HISTORY OF BRAIN SURGERY.

SIR,—In the JOURNAL for last week two of your correspondents take me to task for not referring to the work of Sir William Macwen in my Viennese lecture. It is, I believe, a common custom to read a lecture and not an abstract of it, before criticizing it. I yield to no man in my admiration of Sir William Macwen's contributions to surgical progress.—I am, etc.,

London, W., Jan. 2nd.

C. A. BALLANCE.

THE SEPTAL PERFORATION OF COCAINE-SNIFFERS.

SIR,—Since Mr. O'Malley has spoken for the rhinologists, may I be permitted to affirm that, to many who are not rhinologists, the differences and distinctions between the septal perforations of syphilis, of chronic acid poisoning, and of cocaine sniffing, are well known?

I have never seen a cocaine habitué who was a rag-picker, and I had no reason to suspect my patient of rag-picking, either vocationally or as a vice.—I am, etc.,

London, W., Dec. 24th, 1921.

F. G. CROOKSHANK.

SIR,—Dr. Crookshank writes to complain that I have misquoted him in my letter of December 24th by writing "other competent medical men" instead of "several competent medical men." As this was purely unintentional, I shall be glad if you will insert this correction.—I am, etc.,

London, W., Dec. 29th 1921.

JOHN F. O'MALLEY, F.R.C.S.

A NEW division of biophysics has been established in the department of pharmacology in the Johns Hopkins University. It has been placed in the charge of Dr. J. S. Van der Linden, formerly senior lecturer in applied mathematics in the University of Cambridge.

Obituary.

SIR GERMAN SIMS WOODHEAD, M.D., LL.D.,

Professor of Pathology in the University of Cambridge.

SIR GERMAN SIMS WOODHEAD, K.B.E., Professor of Pathology in the University of Cambridge, died at AisThorpe Hall, Lincolnshire, on Thursday, December 29th, 1921, aged 66. His death will be felt as a personal loss by a large number of the members of the British Medical Association. To his colleagues and to his university the news of his death, although not unexpected, came as a great shock. The charm of his personality was great; even to meet him once was a pleasure, to know him a privilege.

He was the eldest son of the late Joseph Woodhead, formerly M.P. for Spen Valley, editor and proprietor of the *Huddersfield Examiner*. Educated at Huddersfield College and Edinburgh University, he took the degrees of M.B., C.M. in 1878. In 1881 he proceeded M.D., and obtained for his thesis the gold medal. He studied also in Berlin and Vienna, and in 1882 became F.R.C.P. (Edn.). As a student he was an ardent sportsman, and was pre-president of the Edinburgh University Club for many years. He played keenly by football, and was a good short distance runner. There is a tradition that he was "clocked" to do the 100 yards in 10 seconds dead. In later years he was fond of golf and played a fair game.

He was a keen volunteer and became a captain in the V.M.S.C. in 1886; he was promoted major in 1902. Later he held the rank of lieutenant colonel R.A.M.C., T.F. (Sanitary Section), and in 1917 was gazetted brevet colonel, Army Medical Service. On the outbreak of war in 1914 Professor Woodhead immediately placed his services at the disposal of the War Office. As sanitary officer he at once took up the question of pure water supply, testing all the wells in the East Anglian Division for possible contamination and pressing upon the authorities at the War Office the efficiency of the method for sterilization of water by chlorination, on which he had done much work and was an authority. This method, as is well known, was adopted with great success by the Overseas and Home Forces. In connexion with this he devised a plan by which it was possible, by a simple chemical test, for an advance water party to decide how much chloride of lime must be added to 120 gallons of water (the usual capacity of the army water wagon) to render it innocuous. In October, 1915, he took up the duties of medical officer in charge of the Irish Command Depot, Tipperary, and during the period for which he held this command he was twice mentioned for special war services. In 1917 he was appointed Inspector of Laboratories in Military Hospitals in the United Kingdom, having formerly been Adviser in Pathology to the War Office. His work in connexion with the Command Depot was too heavy, and there is no doubt that this overwork and great strain was the commencement of the breakdown in his health, which assumed a serious aspect after his appointment as inspector, an appointment which involved frequent and long journeys, both by train and motor. For these military services he received the K.B.E. in 1919. He relinquished his commission on account of ill health on November 11th, 1919, retaining his rank.

Professor Woodhead was devoted to his profession, and took keen interest in all its branches, doing his utmost to help in their organization and progress, and—as the following statement of his appointments and honours will show—this help was appreciated by those in a position to recognize it. After qualifying, he became Demonstrator of Pathology in Edinburgh and later was a Research Scholar of the Grocers' Company. From 1837–1890 he was Superintendent of the Laboratory of the Royal College of Physicians, Edinburgh. In 1890 he was appointed Director of the Laboratories of the Conjoint Board at the Royal College of Physicians and Surgeons in London. This post he held until his election to the Professorship of Pathology in Cambridge University in 1899. Two years previously he had been awarded the Stewart Prize of the British Medical Association. In all these posts he was an enthusiastic organizer and worker, spending long hours in the laboratory and giving much thought to make the investigations carried on by himself and other workers successful. It was, perhaps, his misfortune that in all three appointments he had to fit up and organize the laboratories of which he was in charge. This naturally occupied much time and thought during the early years of his directorship both in Edinburgh and London, and on his appointment to the chair of pathology in Cambridge he at once set to work to collect funds for the building and

equipment of the present medical school, the plans and necessary equipment of which he personally supervised.

Both as a director and professor he was one of the most approachable and sympathetic of chiefs, listening with patience, helping with pleasure, giving generously time and money, showing great tact in the smoothing out of difficulties. He was loved both by colleagues and staff.

Whilst in Edinburgh he published the first edition of his well known book *Practical Pathology*. This work has passed through four editions, the last of which appeared in 1910. In 1895 he published *Pathological Mycology*, and in 1891 another work on *Bacteria and their Products*. Whilst Director of the Research Laboratories of the Conjoint Board in London he did much work on diphtheria and on the standardization of diphtheria antitoxin. The results of this are embodied in an important report to the Metropolitan Asylums Board on the bacteriological diagnosis and the antitoxic serum treatment of cases admitted to the hospitals of the Board during the years 1895 and 1896. In 1895 he drew up a report to a Royal Commission on Tuberculosis, for which he was an investigator.

In July, 1901, at the British Congress on Tuberculosis for the Prevention of Consumption, Professor Robert Koch made the important statement that "human tuberculosis differs from bovine, and cannot be transmitted to cattle," and further stated that "though the important question whether man is susceptible to bovine tuberculosis at all is not yet absolutely decided . . . one is nevertheless already at liberty to say that if such a susceptibility really exists the infection of human beings is but of a very rare occurrence." As a result of this statement Professor Woodhead, at the meeting, suggested that the members of the Congress should, through representatives, approach the Minister of Agriculture, or President of the Local Government Board, to see if something could be done to settle this very important question. In the following year, 1902, a Royal Commission on Tuberculosis was appointed to test the statement by Professor Koch, and Professor Woodhead was nominated a member. In the work of this Commission he took a great interest, and to it devoted much time. The important results of its inquiries are well known. Woodhead's interest in tuberculosis was maintained to the day of his death. In 1902 he was elected Honorary Fellow of the Henry Phipps Institute, Philadelphia, founded for the study, treatment, and prevention of tuberculosis, and in 1903 Woodhead gave a lecture on this subject in Philadelphia. In the year 1908 he exhibited at the Sixth International Congress on Tuberculosis at Washington a very fine collection of specimens showing the changes produced by tuberculosis in various organs, both in human and animal subjects; for this collection he was awarded a Gold Medal by the Congress. In recent years he gave much time and energy to the organization and support of the Cambridgeshire Tuberculosis Colony at Papworth Hall, and in 1920 he published, in collaboration, a book entitled *Industrial Colonies and Village Settlements for the Consumptive*. His deep interest in the cause of temperance was well known.

Woodhead was the first editor of the *Journal of Pathology and Bacteriology*, the official organ of the Pathological Society of Great Britain and Ireland. He founded it in 1893, with Mr. Y. J. Pentland, and continued in its editorship until towards the end of 1920. In an editorial article in the number for January, 1921, the statement was made:

"It was by his generosity and his practical interest in the inception of the Pathological Society of Great Britain and Ireland that the journal became the official organ of the society. . . . To the interests of the journal, as those who have been associated with him in its conduct best know, he has devoted the same unremitting effort and self-sacrifice. In this work he has won for himself the gratitude and personal affection of contributors all over the world."

In addition to diphtheria and tuberculosis, Professor Woodhead was much interested in the modern studies of diseases of the heart, and was one of the early possessors of an electro-cardiograph which he installed in the Pathological Laboratory at Cambridge; later on the instrument was connected to the wards of Addenbrooke's Hospital by special cable. He devoted much time to the elaboration of a special apparatus for the study of continuous temperature records in man and animals, and published a series of articles on the results obtained by its use. The establishment of the Cambridge University Field Laboratories was also largely due to his efforts.

In teaching, lecturing, and demonstrating he took the greatest interest and pleasure. To the preparation of his

lectures he devoted much time, paying great attention to diagrams and lantern slides to illustrate them. He was a good teacher and one of the best morbid histologists we had. His textbook, above mentioned, will remain a lasting record of his knowledge and work on this subject and will not be readily superseded.

Sir German Woodhead was a Fellow of Trinity Hall, Cambridge, Fellow of the Royal Society of Edinburgh, Fellow and Past President of the Royal Microscopical Society, Vice-President of the Pathological Section of the British Medical Association Meeting in Cambridge in 1920, and Hon. LL.D. of Birmingham and Toronto Universities. On three other occasions he held office in the Section of Pathology at annual meetings of the British Medical Association, and in 1892 he gave the Address in Bacteriology at Nottingham. In 1881 he married Harriett, second daughter of James Yates of Edinburgh, who survives him.

To write an appreciation of his character is difficult. It would include so many of the virtues, but his great love for children and of mankind generally, his unselfishness, his innate desire to help others, his deep religious belief, must be recorded, and for those who wish a further insight into his nature we may quote the following verse: "The fruit of the Spirit is love, joy, peace, long-suffering, gentleness, goodness, faith."

We have received the following appreciation from one of his colleagues at Cambridge:

On December 20th Colonel Littlewood, having two days before finished his full part in the surgical examinations at Cambridge, passed away in heart failure, after but a few hours' illness. On the 29th, Sir German Woodhead, also seeking rest after a hard term's work, passed away suddenly in like manner. For twelve months or more Woodhead—for he is now beyond our titles—had been far from well, at one time dangerously ill; and it was known that behind his apparent recovery lay an injury to his heart of so grave a kind as to make his life very insecure. The present writer, thus bereaved almost at one stroke of two of his oldest and dearest friends, would have borne this sorrow in silence had he not been called upon to pay some poor tribute to one of them. Woodhead's distinction was twofold: the light of his character was so radiant as perhaps to throw his high attainments as a man of science into some shadow. The man outshone the accomplished scientist; and this perhaps the more as, in his utter forgetfulness of self, he was ever ready to bear any burden that his friends might put upon him. Some of us who know him best would beg that Woodhead might not be asked to help in this or that project, for inevitably he would undertake new duties reckless of his own diminishing strength, and perchance of the disadvantage of his work as a whole. Let it not be supposed that Woodhead was merely an amiable, kindly person of an obliging disposition; those who knew him well were aware in him of qualities of high temper and strong will—qualities which in his youth had made him a champion in running and football, but which, devoted later to unselfish ends, issued in a beautiful life. Ardent but no fanatic, as a true Liberal he granted fully to others the freedom he claimed for himself.

Again, it must not be supposed that Woodhead was Professor of Pathology in virtue only of beauty of character. Immersed as he was in public affairs, carried as he was hither and thither by the needs of others, never unheard, his attainments as a pathologist were worthy of his high position. If by his unselfish devotion to many causes, especially during the war, the growth of his department had some times to fend for itself, his command of his subject, his energy, and his powers of ready and lucid exposition were nevertheless exceptionally great. Many a time, in seeking his aid in pathological difficulties of any kind, the present writer had occasion to admire his acquirements, skill, and experience. His strongest subject was no doubt morbid histology, which he would set forth with clearness and precision, illustrating his words by dextrous little sketches. The fourth edition of his *Practical Pathology*, illustrated almost entirely by original drawings, is a very valuable book. Readers of this JOURNAL may remember at the Newcastle Meeting of the Association last year, the beautiful series of drawings of arterial syphilis executed by his assistant Mr. Gillings, after his own preparations and sketches. With his usual magnanimity he would not allow his own name to appear on the exhibit, but only that it came from the Cambridge Pathological Laboratory. His pupils have told me that throughout his official career he always dissuaded them from making those recognitions of the

Professor's advice and assistance which are usual and becoming in scientific papers issuing from his laboratory.

As a few instances of combined humane and scientific work may be mentioned Woodhead's researches and report in the Tuberculosis Commission, the work with Varrier Jones, and, after Gamgee, on diurnal normal and hectic temperatures, the establishment of the Papworth Colony, and, in another sphere, the chlorination method of water purification for troops. His indefatigable labours in the war seem indeed to have caused or contributed to the failure of his health.

In the void of the death of our colleague we lament the loss of the beneficent example of one who was not only a profound student of science, not only an inspiration to all his fellow workers, but also one who saved his life by losing it for his friends, his university, and his country.

G. A.

JOHN ELLIOTT, O.B.E., M.D., F.R.C.P.,

Honorary Physician, Chester Royal Infirmary.

Dr. JOHN ELLIOTT, who died on December 19th at the age of 69, after a serious operation, was one of the leading consulting physicians in Cheshire and North Wales, and his death is a great loss to the medical profession there. Born at Whitehall, Salop, he was educated at Owens College, Manchester, and at St. Bartholomew's Hospital, where he won an open scholarship in science. He graduated B.Sc. Lond. (with honours) in 1880, M.B. Lond. (gold medal) in 1885, B.S. (gold medal) in 1886, and M.D. in 1888. In 1884 he had taken the diploma of M.R.C.S. Eng., and he proceeded to the Fellowship in 1886; he took the diploma of M.R.C.P. in 1891, and was elected a Fellow of the Royal College of Physicians in 1928.

Dr. Elliott held resident posts at St. Bartholomew's Hospital and at Birmingham General Hospital; he commenced practice in Chester some thirty years ago, and soon established a high reputation as a consulting physician. He was appointed honorary physician to Chester Royal Infirmary in 1895, and flung all his energies into the reorganization of that old institution, founded in 1755, so that it could take a foremost place among modern provincial hospitals. A formidable scheme was successfully carried out, and the renovated buildings and additions were opened by the King in 1914.

On the establishment of a venereal clinic Dr. Elliott was appointed its medical officer, and it was arising out of these duties that his name recently came into much prominence on account of his protest in the High Court against disclosing the confidences of a patient. He took part in the subsequent discussion of the subject at the annual meeting of the British Medical Association in Newcastle last July. He was an old member of the Association, had been chairman of the Chester Division, and was at the time of his death president of the Lancashire and Cheshire Branch. He had shown much interest in the organization of the medical profession, and published in the *BRITISH MEDICAL JOURNAL* (SUPPLEMENT, April 2nd, 1921, p. 89) an article suggesting a scheme of medical services for his own district.

During the war Dr. Elliott took a leading share in Red Cross work in the Chester district, and in addition to attending the wounded in the Royal Infirmary he acted as visiting physician to the important Chester War Hospital and as consulting physician to a large number of military camps and Red Cross hospitals in the area. He contributed to medical literature on a wide range of subjects, and he took great interest in antiquarian matters and in medical history. When colour photography was still in the experimental stage he became much interested in it, and many of the photographs he obtained were of high excellence. He was proud to have placed on record the work of Dr. John Haygarth, physician at the Chester Royal Infirmary from 1767 to 1798, who was the first to isolate fever cases in a ward of a hospital and made important pioneer researches on fevers; he published an illustrated article on Haygarth's life and work in this *JOURNAL* (February 1st, 1913, p. 235).

In his professional work Dr. Elliott's great skill in diagnosis was especially recognized by his colleagues, and in this his natural intuition was supported by his sound scientific knowledge and his employment of the most modern methods. He had fitted up a well-appointed private laboratory attached to his residence and there carried out many clinical investigations on questions arising during the course of practice. Robust in appearance and of a cheerful and confident disposition he was a physician for whom his patients and

medical colleagues had affection as well as admiration. He leaves a widow and a family of three daughters and a son.

A colleague writes: The death of Dr. Elliott of Chester, which occurred after an illness of only two days, has produced a feeling of dismay amongst a large circle of friends and colleagues in Cheshire and North Wales, and a distinct blank in the ranks of the profession. After a brilliant career at Owens College, Manchester, and St. Bartholomew's Hospital, Dr. Elliott settled down to the practice of his profession in Chester, in spite of the desire of friends and relatives to see him in a larger sphere. A man of very great force of character and high intellectual capacity, he soon established a consulting practice which extended over a very wide area. He had great energy and driving power, and a wide interest which found outlet in archaeology, photography, radiology, and natural science. The rebuilding of the Chester Royal Infirmary is a standing example of his energy and influence, as it was largely due to his efforts that this work was successfully carried through. He had the faculty of inspiring confidence in his patients and brother practitioners, and gave freely of his knowledge and experience for the benefit of both. He did all his own laboratory, x-ray, and photographic work, and never spared himself in any way if he could relieve a patient. Having once set his mind on an object he never rested until he had attained his end. He will be missed by a large circle of friends and colleagues in and around Chester, but nowhere more than at the Chester Royal Infirmary, which owes so much to him.

REGINALD ANSTRUTHER FARRAR, M.A., M.D. OXON.,

D.P.H. CAMB.

On July 31st last Dr. Reginald Farrar retired from the appointment of Medical Officer of the Ministry of Health, and in November, under the auspices of the League of Nations and the League of Red Cross Societies, he went to Russia to assist Dr. Nansen in organizing the arrangements for famine relief in that country. Last week one of his old colleagues received a letter from him, in which he said he was not well, that his temperature was 102° F., and he anticipated he was "in for" a severe attack of illness. Information reached the Ministry on December 30th, 1921, that he had died the previous day at Moscow. The cause of his death is believed to have been typhus fever.

Reginald Farrar was the eldest son of the Reverend Frederick William Farrar, well known as Dean Farrar. He was born at Harrow in 1861, went to Marlborough School, and in 1880 matriculated at Oxford and entered Keble College. He took his B.A. degree in 1883. It was originally intended that he should take Holy Orders, but though always a religious man and actuated by the purest principles he felt that he could not subscribe to the thirty-nine articles of the Established Church; he therefore turned his attention to medicine and became a medical student at St. Bartholomew's Hospital. His loosely tied and flowing red cravat, strident voice, unconventional manner, enthusiasm, impulsiveness, and happy disposition, made him a well-known student at the hospital. He took the diplomas of M.R.C.S. Eng. in 1887, and of L.R.C.P. in 1888, and graduated M.B., B.Ch. Oxon. in the following year; he took the M.D. in 1893. He served as house-surgeon to Mr. (afterwards Sir William) Savory. On leaving St. Bartholomew's Farrar studied for a short time in Vienna and then went into general practice at Stamford in Lincolnshire, where he married Miss Mapleton the daughter of the Rector of Stamford. He took the D.P.H. in 1897. Private practice in the country proved uncongenial to his temperament and love of adventure, and in 1899 he was appointed by the Government of India one of the medical officers for plague and famine duty in that country. On his return to England he studied public health administration under Dr. Allan, then medical officer of health for the Strand District and now for the Metropolitan Borough of Westminster. In conjunction with Dr. Allan he published a book on *Aids to Sanitary Science*. Subsequently, whilst continuing his interest in public health work, Reginald Farrar occupied himself in private practice at Chiswick for about a year, but in 1903 he was appointed a medical inspector of the Local Government Board.

Several of his official reports on the sanitary circumstances and administration of districts and on the prevalence of disease, including those on enteric fever in the Ashington Urban District in Northumberland, outbreaks of disease affecting the cerebro-spinal system in the Midland Counties

UNIVERSITY OF LONDON.

The following have been recognized as teachers of the University in the subjects mentioned and at the institutions indicated:

University College.—Dr. Charles S. Macer (Histology of Medicine).
St. Thomas's Hospital Medical School: Mr. J. E. Adams (Surgery), Dr. E. Farghular Buzard (Medicine), Sir Archibald D. Reid, K.B.E., C.M.G. (Ear, Nose, Throat), Mr. Zebulun Mennell (Anaesthetics).
Middlesex Hospital Medical School: Mr. Hasmond E. Apperly (Anaesthetics), Mr. A. S. Blundell Hankart (Surgery, Orthopaedics), Dr. T. Izod Bennett (Medicine), Dr. Henry MacCormac (Dermatology).

A letter has been received by the Academic Council from the Dean of the London Hospital Medical College intimating that it had been decided to limit admission to that College to men students only in the future.

In connexion with residuary estate of the late Miss F. J. Wedgwood, which was applicable for the benefit of animals, it was reported an Order of the High Court of Justice, Chancery Division, made on May 27th, 1921, had allotted stock of the nominal value of about £3,500 to the University for the benefit of the Brown Animal Sanatory Institution.

The University Medal at the M.B., B.S. examination for internal and external students, October, 1921, has been awarded to Geraldine M. Barry of the London (Royal Free Hospital) School of Medicine for Women.

Mr. A. G. R. Foulerton will give a public lecture at University College on administrative measures for the improvement of the public health, on Monday, February 13th, at 5.15 p.m.

A course of four lectures on the evolution of man will be delivered by Professor G. Elliot Smith, F.R.S., at University College, on Fridays, February 3rd, 17th, and 24th, and March 3rd, at 5 p.m.

UNIVERSITY OF EDINBURGH.

The following candidates have passed the examination for the diploma of Tropical Medicine and Hygiene:

J. H. Clarke, K. A. Giechrist, G. J. I. Lintlater, Captain N. B. Morris, M.S.

UNIVERSITY OF ABERDEEN.

The following candidates have been approved at the examination indicated:

FINAL M.B., Ch.B.—C. A. Aymer, Isabel M. G. Bisset, W. S. Cochar, H. B. Cook, A. J. Carr, Nellie S. Diack, Isabella R. Gordon, J. Grant, W. P. Jordan, D. F. McGregor, N. M. MacLennan, R. MacLeod, J. W. MacLennan, J. Meldrum, W. J. Meldrum, J. J. Milne, V. E. Milne, W. G. Murray, J. D. Cole, J. Rennie, C. Reid, H. Ritchie, G. Shapiro, J. C. Souter, Harriet J. S. Taylor, M. Taylor, V. M. M. Watson, Anne T. West.

* With distinction. † With second class honours.

UNIVERSITY OF ST. ANDREWS.

The following candidates have been approved at the examination indicated:

FOURTH M.B., Ch.B.—Medicine: T. K. Buchanan, G. R. M. Corlimer, Katharine D. Macfarlane. Surgery: T. K. Buchanan, G. R. M. Corlimer, Nona B. Lesslie, J. N. D. Smith, Margaret H. R. Young. Midwifery: G. G. Buchanan, T. K. Buchanan, Katharine M. Campbell, H. Fisher, Phyllis Fennig, Gracie M. McIlroy.

The Services.

ARMY OF OCCUPATION BONUS FOR R.A.M.C. OFFICERS IN INDIA.

The following extract from Army Instruction (India) No. 917, of December 6th, 1921, refers to the grant of the Army of Occupation bonus to Regular, Special Reserve, and Territorial Officers of the R.A.M.C. serving in India:

"In partial modification of paragraph 3 of Army Instruction (India) No. 214 of 1920, it has been decided, with the approval of the Secretary of State for India, that all Regular, Special Reserve, and Territorial Force Officers of the Royal Army Medical Corps who served in India shall be granted the Army of Occupation Bonus in addition to the rates of pay authorized in that Instruction, for the period July 1st to December 31st, 1919."

AUXILIARY R.A.M.C. FUNDS.

The usual quarterly committee meeting of the Royal Army Medical Corps Funds was held on December 16th, 1921, at 11, Chandos Street, Cavendish Square. Nine grants were made to cases in the benevolent branch for the orphans of officers, amounting to £605 14s., and twenty grants in the relief branch for widows and children of the rank and file, amounting to £705 0s. 4d.

These funds are for the relief of widows and orphans of commissioned officers, non-commissioned officers, and men of the rank and file of the Royal Army Medical Corps, Special Reserve, Territorial Force, and New Armies, and also for the relief of the children of those who have been so severely damaged in the late war that they need help for the education of children. Requests for relief should be addressed to the Honorary Secretary, at the offices of the funds, 11, Chandos Street, Cavendish Square, W.1.

TERRITORIAL DECORATION.

The Territorial Decoration has been conferred upon the following officers of the R.A.M.C. (T.A.) under the terms of the Royal Warrant dated October 13th, 1920: Colonel H. T. Semmel, D.S.O.

A.D.M.S., Welsh Division. Lieut.-Colonels Charles E. Douglas, V.D. (Honorary Captain in Army), attached 7th Division, Black Watch, and Richard M. West, D.S.O., O.B.E., 2nd North Midland Field Ambulance. Majors G. W. Molotosh, attached 6th Battalion Royal Highlanders, William Dyson, O.B.E., attached 7th Battalion Lancashire Fusiliers (retired), and Eric D. Gairdner, D.S.O., attached 5th Battalion, Royal Scottish Fusiliers.

Medical News.

SIR JAMES KINGSTON FOWLER will deliver an Emeritus Lecture at the Middlesex Hospital Medical School on Friday, January 20th, at 3 p.m. The subject of the lecture is "Diagnosis."

SPECIAL courses of systematic lectures and clinical demonstrations will be given at the National Hospital for Diseases of the Heart, Westminster Street, W.1, during January, February and March. The fees are £2 2s. a month or £5 5s. for three months. Further particulars can be obtained from the Dean, Dr. P. Hamill, at the hospital.

AT a meeting of the Society for the Study of Inebriety, in the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, W., on Tuesday, January 10th, at 4 p.m., Dr. Charles F. Harford will open a discussion on "Racial aspects of alcoholism with special reference to the coloured races." Members and Associates may introduce visitors.

MR. BASIL HALL, on the completion of his twenty years' period of service as honorary surgeon to the Bradford Royal Infirmary, has been appointed honorary consulting surgeon. The Board of Management has also passed a resolution expressing its most cordial and grateful thanks to Mr. Basil Hall for his valuable services as honorary surgeon, and for the practical interest he has shown in matters affecting the welfare or advancement of the hospital and his strenuous efforts towards the erection of a new infirmary.

THE honorary freedom of Carnarvon has been conferred upon Dr. R. Parry, J.P., a former Mayor of the town, in recognition of his services as a member of the town council for thirty-three years, and of the part he has taken in many local movements; the honour had been previously conferred on seven occasions only.

THE Council of the Röntgen Society is arranging a joint meeting with the Institution of Electrical Engineers and the Electro-Therapeutic Section of the Royal Society of Medicine to be held before the end of the present session. Particulars will be announced as soon as definite arrangements have been made.

COLONEL W. W. O. BEVERIDGE, C.B., Professor of Hygiene in the Royal Army Medical College, Millbank, was recently elected a foreign correspondent, and Sir Ronald Ross, K.C.B., F.R.S., a foreign associate of the Académie de Médecine.

DR. H. J. W. MARTIN is retiring from Mill Hill after thirty years' practice there. He and Mrs. Martin were recently presented with a cheque for £468 and a portfolio containing the names of the 560 contributors to the gift.

IT is proposed to make St. Luke's International Hospital, Tokyo, the nucleus of a medical centre comprising a hospital of 250 beds, a training school for 150 nurses, a post-graduate department for training resident medical officers, and for medical research work, a public health department to include medical social service, and a library of British and American medical literature.

THE second Hunterian Society Lecture will be delivered by Mr. Walter G. Spencer, F.R.C.S., on "Some local results of dental infection," at St. John College, Embankment (close to Blackfriars Bridge), on Wednesday, January 11th, at 9 p.m. All members of the medical profession are cordially invited to attend.

AT the last meeting of the executive of the National College of Teachers of the Deaf, Mr. Macleod Yearsley and Dr. Kerr Love were unanimously elected vice-presidents of the college in recognition of their work among the deaf and the valuable assistance they have rendered the college for a good many years past.

THE *Journal of Orthopaedic Surgery* (Boston, U.S.A.) announces that in January it will become a quarterly publication under the name of the *Journal of Bone and Joint Surgery*.

DURING October 1,371 fatal cases of plague occurred in Java, as compared with 1,110 in September, 928 in August, and 439 in July.

DR. N. ANTONI, of Stockholm, has been awarded the Lennmalm prize for 1921 by the Swedish Medical Association; he is the author of a number of important works on clinical neurology.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, Ailology, Westrand, London; telephone, 2630 Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, Mediscera, Westrand London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Biactilis, Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4361, Central).

QUERIES AND ANSWERS.

CONGENITAL DEFORMITY OF TOE.

"W. G. P." asks for information as to the treatment of congenital hammer toe, the third toe, both feet, in a baby 8 months old, both toes are buried by those on either side.

"* We presume that in our correspondent's case the condition is one of congenital flexion and not a true hammer toe. If the malformation is not severe it can probably be corrected by gradual extension on a splint. This should be a T-shaped splint of malleable metal such as duralumin, which can be shaped by the fingers to the control of the plantar surface of the metatarsus and of the toe and fastened with bandages and strapping. This should be worn night and day, but removed frequently for manipulations and in order to see that there is no undue pressure. Sloughing is easily produced if care is not taken. If the case is too severe for this treatment to succeed excision of a wedge from the dorsal surface (including articular surface) of the end of the first phalanx may be done at 2 years old. Such cases should be treated in splints as soon after birth as possible. When the child begins to walk he or she should have sandals with slots for tapes to tie down the toe on a pad under its end."

INCOME TAX.

"I. S." commenced practice in April, 1919, and has been assessed for his second year (1920-21) on the average of the profits of that year and the first year.

"* We see no justification for that procedure. If "I. S." succeeded to a practice then the statutory basis of assessment would be the average of the last two years of his predecessor and his own first-year, subject to the right to an adjustment at the end of the year to the actual profits of the year. If, on the other hand, the practice is a new one then the income is assessable for the second year, 1920-21, on the basis of the ascertained profits for the first year 1919-20."

"C. M. S." inquires whether there is not some additional allowance to which he is entitled on the ground that his wife earns income to the extent of £100.

"* Yes; in addition to the 10 per cent. earned relief on the £100, there is the claim to a separate additional personal allowance up to a maximum of £45, to which "C. M. S." is apparently entitled."

"T. G. E." who is doing Pension Board work, has recently started in practice as a radiologist and electrotherapist. So far the expenses of his practice exceed the receipts. He asks whether he can set off the loss against the fees from pension work.

"* The fees are assessable separately, and as a matter of assessment the loss cannot be deducted. But our correspondent is entitled at the end of the year of assessment to an adjustment in respect of the tax paid by him as against the amount that would have been payable if the loss for that year had been deducted. Two points should, however, be borne in mind: first, that cash receipts only may not represent the full "income" of the new practice, and second, that an amount of loss allowed for at the end of the year cannot be brought into future averages as a minus quantity."

LETTERS, NOTES, ETC.

THE MEDICAL ASPECT OF RELIGIOUS REVIVALS.

DR. J. BOYD PRIMMER (Cowdenbent) writes: Might I suggest a probable reason why the present hectic "revival" in Eyemouth and Fraserburgh, like several which have preceded it, is practically confined to fishermen? To the medical mind consanguinity, or a bad family history intensified by it, suggests itself as a predisposing cause. Intermarriage is prevalent amongst these people, with consequent physical defects and deterioration of mind, rendering them liable to neuropathic disorders. Revivals are invariably accompanied by hysteria—witness similar outbursts in the Welsh valleys, where, I believe, like conditions exist, including consanguinity: each revival produces its crop of religious mania and hysteria amongst those of a neurotic tendency, particularly females. In the case of the fisher folk the males also, being naturally superstitious, are more apt to be carried away by the high tide of emotion, especially when of a religious nature, thus rendering them prone to add sundry embellishments, as did their predecessors at the dawn of the Christian era. Much could be said also for the peculiar psychology of the crowd as a contributory factor. "Your sons and your daughters shall prophesy, your old men shall dream dreams, your young men shall see visions," wrote a prophet of old. So it is to-day: where emotionalism prevails. Some of the Scottish fishermen, to quote an authentic report, actually "have withdrawn the insurance from their boats, and refused to work or pay their debts, in the belief that the end of the world is at hand." But, alas! instead of receiving a call from on high, they are in danger of being served with a summons to the county court. As Savill says in his *Clinical Medicine*, "delusions, especially on religious subjects, are not at all uncommon in the so-called sane. But when these delusions modify the acts or conduct of the individual and lead him to act in an unusual manner the condition becomes one of insanity."

AN EIGHTEENTH-CENTURY ADVERTISEMENT.

DR. W. HARGOOD (Sutton, Surrey) sends the following advertisement which he has found in the *St. James's Chronicle or British Evening Post* for Tuesday, April 19th, to Thursday, April 21st, 1768: It occurs at the bottom of the last column of the front page, and is not distinguished in form from the other news of the day. We are glad to note that the advertiser's name does not look English. The advertisement is as follows:

"Dr. Kofe, at No. 3, near Orange Street, in St. Martin's Street, Leicester Fields, opposite the Blackmoor's Head, takes the liberty to acquaint the public of his discovery of a remedy which radically cures fistulas of all sorts, the most complicated, without the least operation by any instrument in fifteen or eighteen days. He possesses a vegetable essence which dissipates in less than two minutes the most violent headaches of all kinds, by means of eighteen drops of this essence rubbed with the hand upon the afflicted part, or by taking it up the nostrils. The price of a phial 6s."

He composes a natural balsam which dissipates in a quarter of an hour, or less, the most violent pains of the Gout. This remedy does not make it remount, but fixes it, by correcting the acrimony of the humour, and by relaxing the vessels. The author will communicate with the remedy the method of using it, and offers personally to attend such persons as doubt of the efficacy of this sovereign remedy, and will cure them of the pain while he is present. He likewise radically cures rheumatism of all kinds, scirrhus tumours, disorders of the skin, chronic diseases, consumptions, ruptures, and likewise all maladies incident to the ladies. Venereal complaints are likewise cured in a manner peculiar to himself with the greatest facility and convenience to the patients. He may be seen any morning as above, where his medicines may be had at all hours."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 28, 29, 32, and 33 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 30 and 31.

THE following appointments of certifying factory surgeons are vacant: Girvan (Ayr), Shaw (Lancs), Redditch (Worcester).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post restante* letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

1. Treatment of Beri-beri.

Numerous investigations have, as is well known, shown that beri-beri is a deficiency disease, which frequently occurs by continued living on decorticated rice. WELLS (*Philippine Journ. of Science*, July, 1921) now describes a method whereby the rice polishings can be treated in such a manner as to yield a liquid containing a large proportion of the active antineuritic factor, which can then be used for the cure of cases of the disease. The general technique is to extract the polishings of white rice with alcohol, to separate off the inactive substances obtained at the same time, and to concentrate the fluid to the consistency of a syrup, in which form it is finally collected and dispensed in bottles. The action of this preparation would appear to be highly favourable. It has been used in the Philippine Islands since 1914 in increasing quantities and has proved of great value in the treatment of beri-beri in children. It will be remembered that a similar extract prepared from yeast, and distributed under the commercial name of Marmite, was employed with considerable success amongst the troops in Mesopotamia during the recent war.

2. Brittleness of the Hair.

In *Ann. de Derm. et de Syph.*, November, 1921, SABOURAUD discusses the three diseases, trichoclasia, trichorrhexis, and trichoptilosis, in all of which the hair is found to be excessively brittle. In simple trichoclasia the hair fractures transversely; in trichorrhexis small grey swellings are found on the last few centimetres of its free extremity; when the end of the hair is found to be frayed the name trichoptilosis is applied. This brittle condition of the hair was at one time thought to be due to infection by a parasite, in proof of which the fact was cited that false hair in contact with natural hair would come to manifest the same fragile condition. Sabouraud declares that hair so affected is not diseased; it is suffering from traumatism. The repeated application of basic lotions and strong soaps and alkaline shampoos robs the hair of its protective covering of fat and induces this brittle condition. This state of affairs is very widespread and the usual treatment recommended is the more vigorous application of those very measures which aggravate the traumatism. Sabouraud does not maintain that the wrong use of lotions is the only cause of trichorrhexis, but cases which cannot be explained by the above causes are very rare.

3. Scabies Norvegica.

ACCORDING TO BLOEMEN (*Nederl. Tijdschr. v. Geneesk.*, October 29th, 1921), who records a case in a Rotterdam woman aged 80, scabies Norvegica is a special form of scabies which was described by Boeck and Danielssen in Norway as occurring in lepers, especially old and helpless persons, which affects sites which are atypical for scabies, such as the head, palms, and soles, and after a period of varying duration gives rise to the formation of crumpling masses of scaly crusts. Leprous patients suffer no irritation from the eruption which may last throughout life. Bloemen's patient, who was not a leper, had suffered from considerable itching for some months, but was cured after about six weeks' treatment. Jordaa stated that there were only 32 cases of scabies Norvegica on record in 1914, since when he has seen 2 cases, and Rille of Leipzig has also seen 2, so that with Bloemen's case there is a total of 37 reported cases. As regards the histological picture, according to Török and Unna the mites in scabies Norvegica are found in the stratum corneum only, which is much thickened. Bloemen found that here and there the mites penetrated into the rete Malpighii, giving rise to keratinization. There were also parakeratosis, cellular infiltration of the papillae in the subcutaneous tissue, perivascular infiltration and elongation of the papillae.

4. The Minor Ocular Signs of Diabetes.

TERRIEN (*Paris méd.*, October 22nd, 1921) states that ocular complications in diabetes are frequent and various, being met with in more than 10 per cent. of all cases in the form of lesions of the cornea, iris and choroid, cataract, retinal haemorrhages, changes in the optic nerve, amblyopia, affections of the vitreous, ocular palsies, and palpebral and orbital abscesses. In addition to these serious complications there are certain ocular manifestations, which, though of much less gravity, are of diagnostic value owing to their frequency and

sudden development. Terrien classifies them under the headings of disturbances of accommodation and refraction. Changes in accommodation consist in presbyopia which occurs at an unusually early age, and in more marked cases in actual paralysis of accommodation. In 80 diabetic patients examined by Terrien, 11, or nearly 14 per cent., presented some diminution of the power of accommodation. The changes in refraction consist in either hypermetropia, which in diabetes may develop suddenly without any previous ocular disturbance, or on the other hand a transient myopia, the most probable explanation of which, according to Terrien, is an increase in the refringency of the lens.

5. Early Diagnosis of Pneumonia.

COLE (*Med. Record*, November 19th, 1921) points out that the pitch and timbre of the voice and whisper are always changed in infiltration and consolidation of the lung, and that the ear can detect a patch of infection quite as early as it can be discovered by x-rays. The metallic timbre of the voice in consolidation carries through fluid with even increased intensity, and lung tissue compressed by new growth gives a well-marked change in pitch and timbre of both voice and whisper. In the early recognition of pneumonic infection these changes in the voice and whisper give definite information before there is any appreciable change in the respiratory or percussion sound. Such early commencing limited areas can thus be detected when they are no larger than the chest-piece of a stethoscope, often before the occurrence of sputum, râles, or cough, and at a stage when percussion is of no practical value. While both bronchopneumonia and lobar pneumonia may occur in the same or in different lobes at the same time, a single spot in an individual lobe always indicates a lobar pneumonia. While diagnosis by voice and whisper is absolute and easy, the author admits that frequent corroborative x-ray examinations are of value.

6. Hilum Tuberculosis.

MELVILLE (*Arch. Radiol. and Electrotherapy*, November, 1921) raises some points in the diagnosis of hilum tuberculosis in the adult by means of x-rays, considering that further investigations are needed into the significance of abnormal lung shadows and their correlation to clinical evidence. While clinically the diagnosis rests upon paravertebral areas of dullness, the transverse narrowing of apical expansion, and the fact that the affection is bilateral, confirmation is further obtained by the radiographic appearances of thickening and increased density of both lung roots, with marked narrowing and lessened expansion at both lung apices. Exaggeration of the shadows at the hilum or peribronchial tissue is *per se* of no value as positive evidence of pulmonary tuberculosis, since any irritative affection of the bronchial tube element will produce shadows of equal density and significance. The necessity for the closest co-operation between the clinician and the radiologist is pointed out, the latter being ever on his guard in his interpretation of the clinical significance of hilar and peribronchial shadows.

7. Treatment of Diarrhoea in Tuberculosis by Calcium Chloride.

MERKLEN, DUBOIS-ROQUEBERT, and TURPIN (*Bull. Soc. de Thér.*, November 9th, 1921) state that the use of calcium chloride for the gastro-intestinal complications of tuberculosis was introduced by Mandel, who employed it in 5 per cent. solution. Subsequently Saxtorph raised the strength of the solution to 10 per cent., and Rist and his collaborators Ameyville and Ravina to 50 per cent. The present writers have treated fifteen tuberculous patients suffering from diarrhoea with intravenous injections of calcium chloride in the strength used by Rist. They started by giving 1 gram of calcium chloride and repeated the dose three or four times, if necessary. The results were as follows: Eight patients were regarded as cured, six were considerably improved, and in only one did the treatment have no effect.

8. Acridine Dyes in Dermatology.

KISSMEYER (*Ugeskrift for Læger*, October 27th, 1921) states that trypanfavin has been used for more than a year at the Finsen Institute in Copenhagen, and that the results obtained fully justify the enthusiasm of its early sponsors. The drug is used as an ointment and in both alcoholic and aqueous solution, and a 1 in 1,000 trypanfavin ganze dressing has also been used with success. The diseases reacting most satisfactorily are the various septic conditions of the skin, such as sycosis barbae, folliculitis, and the like, as well as secondary

septic conditions, such as those due to ulcers of the leg. After operations prophylactic painting of the wound with trypanflavine in alcohol has proved effective, and trypanflavine dermatophil (2 in 1,000) is applied to areas of lupus where Finsen treatment has provoked a severe reaction. Trypanflavine has, however, proved disappointing in gonorrhoea.

9. Mercurial Tonsillitis.

ALMKVIST (*Hygiea*, October 31st, 1921), who has observed 26 cases of mercurial tonsillitis in 24 persons (two persons suffered twice since 1906, points out that angina mercurialis is often wholly overlooked or taken for some other disease. He attributes this to the comparative rarity of this form of mercurial poisoning, to its similarity to other diseases of the fauces, and to the scanty notice given this disease by the textbooks. As his records show, angina mercurialis may break out early in the course of treatment, and even when the dosage of mercury has been timid. In other cases it may not occur till some time after the completion of a vigorous course of mercury. The factors determining the development of angina mercurialis are the same as for mercurial stomatitis: there must be a certain concentration of mercury in the tissues, and there must be a luxuriant bacterial flora in crypts and recesses favourable to the persistence of germs. The author has found this second factor so essential to the development of angina mercurialis that he even continues to give mercury after its appearance, provided he can control the growth of bacteria by antiseptics applied locally. He recommends local applications of 50 per cent. silver nitrate, hydrogen peroxide, iodine in alcohol, and a mixture containing equal parts of ether and concentrated sulphuric acid. Intravenous injections of salvarsan may either prove dramatically effective in controlling mercurial angina and stomatitis, or may fail entirely.

SURGERY.

10. Prostatic Hypertrophy.

NIEMEYER (*Deut. Zeit. f. Chir.*, Band 167, Hefte 1 and 2, 1921), who has examined thirty-five enlarged prostates in the course of nine months at the Pathological Institute of Cologne University, has come to the following conclusions: (1) The essence of so-called hypertrophy of the prostate consists, when the lesions are slight, of compensatory hyperplasia in an organ undergoing senile involution. When the changes are well marked there is a tumour formation, such as fibroadenoma or, less frequently, fibromyoma. (2) Fibroadenoma, in which the glandular content is well developed, stand out on section as sharply circumscribed nodules; but when the glandular content in fibroadenoma is scanty, or in fibromyoma, the section on naked-eye examination differs but little from that of the normal prostate, and the diagnosis in such cases is only possible microscopically. (3) Inflammatory processes are a frequent complication, but not the cause, of prostatic hypertrophy. (4) Arterio-sclerosis is not a cause of prostatic hypertrophy, as maintained by French writers. Only 6 of Niemeyer's 35 cases showed arterio-sclerosis of the prostatic arteries, and in only 2 of these were the smaller arteries involved. (5) Niemeyer's view is allied to Virchow's conception of prostatic hypertrophy as a tumour formation, but associates the new growth with senile involution and the subsequent reaction.

11. The Prostatic Syndrome without Evident Enlargement.

HARRIS (*Med. Journ. of Australia*, October 29th, 1921), under the title of *Prostatism sans prostate*, draws attention to a condition where the prostate, though actually smaller than the normal gland, gives rise to the usual prostatic syndrome. This condition is due to the so-called median prostatic bar, and it was found present in 20 per cent. of cases of prostatism seen during a period of four and a half years. Three definite types of median bar formation may be recognized: (1) The glandular bar, the most common type, due to an adenomatous overgrowth in the subcervical group of glands. This occurs as a localized projection in the posterior segment of the bladder sphincter and prostatic urethra. This later may be projected into the bladder and form one type of middle lobe. It differs from the true middle lobe of the prostate in that the true middle lobe is part of a general hypertrophy and grows up outside the bladder sphincter, whereas in the condition described it is wholly within the vesical sphincter. After the sixth decade the two conditions may be associated. The median glandular bar, even when quite small, may cause marked obstruction of the ball and socket type. (2) The fibrous bar is composed of dense sclerotic tissue and is stretched across the vesical orifice; it is due to fibrous degeneration of the muscle of the sphincter. The rest of the

prostate is usually normal. (3) The collar type of obstruction occurs as a circumferential fibrous deposit around the sphincteric orifice causing contraction of the vesical outlet. The prostate as a rule shows a general fibrous degeneration—the so-called small fibrous prostate—and does not, as usually stated, require enucleation. The symptoms resemble those of general prostatic hypertrophy, but no enlargement of the gland is felt on rectal examination, hence the appellation *prostatism sans prostate* of the French. The age at which it occurs is distinctly earlier. Diagnosis is easy to the practised cystoscopist and the changes above described are readily seen. The treatment resolves itself into the removal of the obstruction and treatment of any associated lesions. Suprapubic cystotomy, with the removal of a wedge of tissue from the posterior segment of the vesical neck, was adopted for the collar type in nine cases. The second method described is not satisfactory in these cases. Young's prostatic punch was used in forty-four cases. The obstruction is removed by inserting the instrument along the urethra into the bladder, and the median bar is entrapped and excised. The operation is a minor procedure and can be done under local anaesthesia if desired. Severe haemorrhage occurred in three cases, necessitating a suprapubic cystotomy. The after-results were good and no patient appears to have had recurrence of symptoms. The operation can be performed with safety where open operation would be fraught with grave risk. This operation is, of course, useless in the presence of an associated hypertrophy of the prostate.

12. Radium Treatment of Nasal Polypi.

ACCORDING to LYONS (*Amer. Journ. of Roentgenology*, 1921, vii) the unsatisfactory results which not infrequently follow operative treatment of myxomatous nasal polypi are attributable to the circumstances that the tumours are attached to the mucosa of a turbinate bone or of a sinus by a pedicle which is not well defined, and that even after removal of the tumour, pedicle, and adjacent portion of mucosa, the neighbouring tissue continues to undergo a myxomatous change which leads before long to the appearance of a second polypus. Radium inserted into a nasal polypus does not cause its disappearance, and applied post-operatively does not prevent its recurrence. The use of radium in obstinate cases depends solely on its power of stimulating the production of fibrous tissue, so that after two or three applications the polypus recurs in the form of a fibromyxoma or fibroadenomyxoma, the operative ablation of which is easier. Subsequent recurrences take place at much less frequent intervals. In early cases Lyons applies a 50 mg. tube, packed in by means of sterile vaseline gauze, for two hours. Subsequent treatments are given at weekly intervals.

13. Episcleritis.

SINSKEY, LEVIN, and SACKS (*Archiv. Ophthalm.*, November, 1921) discuss a new method of approach in the treatment of episcleritis, based upon a case which resisted all the usual treatment, and which appeared to be of metabolic origin. No obvious etiological agent was present, but on withdrawal from the diet of carbohydrates in the shape of cereals, potato, bread, and sugar, reducing the fat intake, and allowing moderate amounts of protein and carbohydrates of the vegetable and fruit type, the symptoms disappeared. Any laxity in the diet was followed by recurrence, and it was possible, by giving and withdrawing the forbidden foods, to cause the reappearance and subsidence of the ocular symptoms. On two occasions—one after tonsillectomy and another after a paranasal sinus operation—relief of symptoms occurred for ten and twelve days respectively, which was attributed to the restriction of the offending foods during the post-operative periods when the patient ate very little. The case suggests that in the study of the cause and treatment of cases of episcleritis of obscure origin dietetic factors should be considered.

14. Cardio-tuberculous Cirrhosis (Hutinel's Disease).

CURCHOD (*Rev. méd. Suisse rom.*, October, 1921) states that the disease described by Hutinel in 1893 under the name of cardio-tuberculous cirrhosis corresponds to Kassanul's mediastino-pericarditis. The disease commences in childhood with bronchitis or pleurisy and is followed by enlargement of the liver, ascites, and circulatory disturbance such as cyanosis and swelling of the hands and feet. The disease may also develop insidiously with a primary cardiac symphysis without ever having been preceded by pleuropulmonary or glandular symptoms. On examination of the heart no enlargement or murmur is found, but the apex beat is not displaced and the precordial dullness is the same in inspiration and expiration. The autopsy shows a large cirrhotic liver, pericarditis, pleurisy, and perivascular adhesive mediastinitis. The subdiaphragmatic peritoneum is

is affected. Rutinel main aims that two factors are required to produce the cirrhosis—namely, passive congestion of the form of a nutmeg liver, which occurs in all diseases of heart at an advanced stage, and tuberculous infection. The course of the disease is very slow. The condition must be distinguished from disease of the liver due to syphilis, laria, alcoholism, hydatid cyst, hepatic abscess, and yloid degeneration. Currehod emphasizes the three following points in diagnosis: (1) Disproportion between the signs of cardiac disease, which are almost always negative, and the gravity of the peripheral asystole. (2) Absence of the urinary signs of pericarditis, such as retraction of one or more intercostal spaces. Immobility of the cardiac dullness. (3) Especially of the apex beat should rather be sought for. The distribution of the oedema, which at the onset appears on the face and often on the hands and does not last long, being due to compression of the superior vena cava by the active mediastinitis. Currehod records three cases, in two of which Braner's operation of precordial thoracotomy was performed, in one with satisfactory results and in the other without effect. He considers that this operation should be reserved for cases of adhesive tuberculous pericarditis or for those in which there are no valvular lesions or signs of yloid cirrhosis of the liver. Fever and active tuberculosis could be regarded as absolute contraindications.

15. Stone in the Ureter.

CKENNA (*New York Med. Journ.*, November 2nd, 1921) records a case of stone in the ureter which was voided after lithotripsy. At first seen in the lower calyx of the left kidney the stone eventually became lodged low down in the ureter at its junction with the bladder. The mucus was incised and the ureter dilated twice without result, and about three months later the lower end of the ureter in its course through the bladder was fulgurated, almost all the bridge of membrane, and some of the muscle, being destroyed. No result followed until a fortnight later, when the stone with symptoms of colic and haematuria passed into the bladder and was eventually voided. The calculus measured 2.8 in. at its narrowest diameter, 7.8 in. in length, and 3.8 in. in width, and weighed 17 grains. Pyeluria ion, after subsidence of reaction, leaves no more or less permanently relaxed lower ureter, thus permitting passage when no colic occurs, and, should another stone form, a partly patent ureteral orifice is of value. A month later cystoscopy showed that the orifice was unimpaired in function.

16. Etiology of Acute Infectious Nephritis and Pyelonephritis.

RUNEBOERG (*Finska Läkarsällskapet's Han Uingar*, September and October, 1921) discusses the etiology of the nephritis and pyelonephritis which develop spontaneously and more or less suddenly without any previous history of disease of the urinary system. Having investigated about 250 such cases at his surgical hospital in Helsingfors, he has come to the conclusion that the disease is haematogenous, and that, the kidneys being the chief portal of exit for germs circulating in the blood, it is natural that time and again they should suffer injury during this exit. He found considerable differences in these cases according as infection was due to the coliform group or staphylococci. In the first group 80 per cent. of the patients were females, whereas in barely 20 per cent. of the staphylococcal cases were the patients females. Again in the coliform group bacteriuria was often the last sign of disease; it might, indeed, persist although in every other respect complete recovery had been effected. In the staphylococcal cases, on the other hand, the germs often disappeared from the urine before severe pyuria and other manifestations of infection had subsided. In both groups the disease showed a remarkable capacity for spontaneous cure, and in this connexion the author deprecates hasty operative interference. Unfortunately the coliform cases often relapse even after complete recovery seems to have occurred, and in view of the fact that these cases are often unilateral, at any rate clinically and for all practical purposes, nephrectomy may ultimately prove the best treatment. Of more conservative measures the use of permanent catheterization of one ureter is warmly recommended. Its action is particularly effective in acute cases of pyelonephritis in which inflammation leads to spasmodic closure of the ureter and retention of pus and urine in the pelvis of the kidney.

17. Experiments with Antivenereal Prophylaxis.

GANDACHEAU (*Rev. d'hyg.*, October, 1921) describes four laboratory experiments with a prophylactic ointment of the following composition: Cyanide of mercury 0.075 gram, thymol 1.750 grams, calomel 25 grams, lanoline 50 grams, vaseline 23.175 grams. In the first experiment two drops of the ointment are placed in a watchglass, one drop of a fluid containing active spirochaetes (*Spirochaeta pallida* and spirochaetes of dental tartar) is added, and the ointment

and spirochaetes are carefully mixed. Three or four drops of broth are then added, and the mixture is examined with the ultramicroscope, as well as control suspensions of spirochaetes in the same broth. It will be found that the spirochaetes treated by the ointment are motionless, while the controls retain their movements for several hours. In the second experiment the action of ordinary vaseline is compared with that of the ointment. Two drops of the vaseline and six drops of a suspension of spirochaetes are placed in a watchglass and mixed for a minute with a platinum loop, and in another watchglass six drops of the same suspension are mixed with two drops of the ointment. After ten minutes, at most, all the spirochaetes are motionless in the fluid treated with the ointment, while they still remain active in the fluid containing simple vaseline. The third test consists in inoculating four male rabbits on the prepuce with active spirochaetes and applying the prophylactic ointment to two of the animals one hour after the inoculation. In three weeks' time the two controls showed the characteristic lesions of experimental syphilis, while the two animals treated by the ointment showed no lesions at the end of forty days. The fourth test, which shows the action of the ointment on pyogenic micro-organisms, consists in depositing two drops of vaseline on the inner wall of an agar-agar culture tube on the side opposite the medium. The vaseline is then inoculated with a young culture of *Staphylococcus aureus*, and the mixture is spread over the medium. The same procedure is carried out with the prophylactic ointment in place of vaseline. After two days in the incubator the first tube shows a rich growth, whereas in the second tube no colonies will have formed.

OBSTETRICS AND GYNAECOLOGY.

18. Chronic Inflammatory Conditions of the Fallopian Tubes.

ACCORDING to CURTIS (*Amer. Journ. of Obstet. and Gynec.*, November, 1921), gonorrhoeal infection is responsible for at least three-fourths of all inflammatory lesions of the Fallopian tubes. Such an infection usually runs a quickly self-limited course, and provided two weeks have elapsed since the return of temperature and leucocyte count to normal, modern cultural methods fail to yield growth when the entire diseased tube is thoroughly ground and inoculated into culture media. It is permissible to conclude that the Fallopian tube is not a focus for chronic gonorrhoeal infection; there is, however, possibility of repeated infection from without or recurrent invasion of bacteria from the chronically infected lower genital tract. The next most frequent variety of infection is that due to various types of streptococci; tubal infection forms usually an inconspicuous part of the clinical picture, and perisalpingitis is the most common type of lesion, although typical salpingitis, and notably hydrosalpinx, occur with moderate frequency. Thierentosis, exclusive of generalized tuberculous peritonitis, is next most common, and is likely to be overlooked if routine microscopical examinations be not made. Infections with bacteria of the colon and other groups are comparatively rare; *B. coli*, although frequent in large tubo-ovarian abscess, is of little importance as a primary cause of salpingitis.

19. Gangrene of a Uterine Myoma after the Menopause.

LOUBAT (*La Gynec.*, July, 1921) records the case of a woman, aged 52, who two years after the menopause suffered from pain in the lower abdomen unaccompanied by fever, vomiting, or discharge. The general condition was good, and examination showed only a rounded mobile tumour in connexion with the corpus uteri. Histological examination of the specimen after removal showed a myoma exhibiting necrobiosis and gangrene; the cause of these complications could be found in a subcapsular haemorrhage 3 to 4 mm. in thickness which surrounded the tumour. This case is quoted in further proof of the statement that after the menopause retrogression or quiescence of myomata is not the invariable rule.

20. Treatment of Pregnancy Toxaemias by Intravenous Injections of Sodium Chloride and Carbonate.

VOX OETTINGER (*Zentralbl. f. Gynäk.*, October 22nd, 1921) records two cases of pregnancy toxaemia, characterized by albuminuria and diminished secretion of the urine, in which diuresis was re-established and toxic symptoms disappeared after intravenous injections of a solution of 14 parts of sodium chloride and 10 parts of sodium carbonate dissolved in 1,000 parts of distilled water; rectal injections were also employed containing 14 parts per thousand of sodium chloride and 20 parts of sodium carbonate. This treatment is substantially that advocated for nephritis and oedema by Fischer, who seeks to explain the occurrence of both as due to

Increased acidity of the tissue (renal and other), with consequent physico-chemical alterations leading to swelling of the cells and cell membranes. Von Oettingen endeavours to explain on a somewhat similar physico-chemical basis both the toxæmic nephritis and also the eclamptic conditions which may complicate pregnancy. In normal pregnancy the colloidal stability of the blood plasma is diminished, and Fahrén has shown that the sedimentation rate of the erythrocytes is increased. In eclampsia these findings are exaggerated, and a swelling of the cells, and especially of vascular endothelial cells, is demonstrable in the kidneys and other viscera.

21. Indications for Caesarean Section.

ACCORDING to SCHIFFMANN (*Zentralbl. f. Gynäk.*, October 22nd, 1921), Caesarean section may be indicated (a) in the maternal interest, when the true conjugate diameter is 6 cm. or less—an absolute indication; (b) when in the interest of mother or foetus it is desirable to avoid the process of labour—for example, in contracted pelvis, pelvic tumours, placenta prævia, maternal cardiopathy; (c) when the interest of the mother demands speedy termination of pregnancy, as in eclampsia, nephritis, premature placental detachment (accidental haemorrhage), endemic encephalitis; (d) in the interest of the child, in certain cases in which it is probable that natural labour would diminish considerably its chances of viability. As examples of the fourth group of cases, in which the Caesarean operation is described as "prophylactic," the writer records the cases of (1) a primipara, aged 38, with long narrow rigid vagina and a true conjugate of 9.5 cm., breech presentation; (2) a two-para, aged 42, whose first labour, occurring six years previously, had terminated in instrumental delivery of a stillborn foetus, weighing 4,000 grams; the conjugate measured 9.5 cm.; (3) a two-para, aged 35, married eight years, whose previous labour had given a stillborn foetus weighing almost 4,000 grams. These cases, in which the mothers, ardently desiring to have a living child, elected to undergo a Caesarean operation, terminated in live births, without maternal mortality. Schiffmann concludes that in cases in which the patient has had one or two pregnancies terminating in natural labour which in spite of skilful treatment has ended in the birth of a dead child, has shown relatively small degree of ability to conceive, and is nearer the end than the beginning of the reproductive period, Caesarean section is justifiable quite apart from the presence of pelvic contraction, provided that infection of the genital tract can be excluded.

PATHOLOGY.

22. The Pathogeny of Volkmann's Syndrome.

ACCORDING to DENUÉ (*Gaz. hebdomadaire de Médecine de Bordeaux*, September 25th, 1921), the pathogeny of Volkmann's syndrome includes more than ischaemia. The cases in which ischaemia alone is present are examples of flaccid paralysis. In those in which contractures and dystrophy occur, especially transformation into fibrous tissue, the sympathetic plays an important part. Marie, Meige, and Benisty have recently shown that certain reactions of the nerves, especially those of a painful nature, are peculiar to nerves with a nutrient artery or to those situated in the neighbourhood of a large artery. At the same time that an injury affects a vessel, whether it produces ischaemia or not, it injures the fibres and ganglia of the perivascular sympathetic sheath. Even in the absence of a wound in the strict sense of the term the fibres and ganglia of the perivascular sympathetic may be affected by mere compression of the limb. The influence of the sympathetic in Volkmann's syndrome cannot therefore be denied. In cases which require operation, sympathectomy according to Leriche's method, should be associated with tenoplasty.

23. A Method of Obtaining a Homogeneous Culture of the Tubercle Bacillus.

VAUDREMER, who was recently able to grow certain strains of *B. tuberculosis* on ordinary agar, now (*C. R. Soc. Biologie*, December 10th, 1921) claims to have succeeded in obtaining a homogeneous culture of this organism by seeding it into the depths of a medium of potato broth. If a small piece of the surface film of a growth on this medium is transplanted to a fresh flask and immersed below the surface it is found that in forty-eight hours there is an abundant growth, producing a uniform turbidity and consisting microscopically of numerous separate immobile bacilli. In shape they resemble the bacteria on the nodes of the Leguminosae; some are branched, some show a moniliform appearance, some are ovoid, and some recall the aspect of capsulated diplococci. They are readily stainable by Gram's method. On the other hand, they have lost the capacity of retaining the stain in

Ziehl-Neelsen's method. Yet they are easily agglutinable by an antituberculous serum. Moreover, when seeded on to glycerol potato they furnish a growth in ten days of typical tubercle bacilli. Injected into the guinea-pig they fail to give rise to any reaction, either local or general. He has assured himself that no question of contamination entered into these changes.

24. The "Nitritoid Crisis."

A SUGGESTION is put forward by POMARET (*La Médecine*, November, 1921) to explain the genesis of the condition of shock which not infrequently occurs after injection of the arsenobenzol compounds, and which from the coincident lowering of the blood pressure accompanying it has been named the nitritoid crisis. His physiological researches go to show that the chief factor involved is the phenol radical in the arsenic preparation. If a solution of "606," which is normally slightly acid, be added to an albuminous solution *in vitro*, a precipitate occurs consisting of a combination of the protein with the arsenophenol; this precipitate is soluble in alkalies. If given *in vivo* the "606" is able in certain cases to give rise to an intravascular flocculation of the minute colloidal particles suspended in the plasma with the resulting production of a marked fall in blood pressure. Not only, however, has he been able to obtain these effects with "606," but by using phenol alone or trinitrophenol the same fall in blood pressure has been reproduced. He therefore considers that the nitritoid crisis can be explained by the simple physical alterations ensuing in the blood on the introduction of a compound of phenol, and to express this meaning he would call the condition one of "phenolic shock." Unfortunately, an absence of experimental data precludes one from criticizing such a conception as this. It would appear, though, from the paper that the sole criterion he adopts for the presence of a condition of shock is a fall in blood pressure; if no other considerations than this are taken into account, it would be possible to produce shock with any one of the numerous vaso-dilators, one of which—namely, trinitrophenol—he himself uses to support his theoretical explanation.

25. Identity of Antibodies.

ZINSSER (*Journal of Immunology*, September, 1921) discusses what is known as the "unitarian" view of antibody production. He points out that precipitins, agglutinins, lysins, opsonins, and complement-deviating substances are only manifestations of the behaviour of sensitized antigen under different environmental conditions. There is no essential difference in the nature of the antibody; the difference is in the physical state of the antigen itself. Thus, if the antibody comes in contact with finely divided antigen, as in a bacterial extract, and if electrolytes are present and the necessary physical factor furnished by the presence of the serum, then precipitation occurs. On the other hand, when dealing with whole bacteria of relatively large mass and correspondingly small surface exposure, then agglutination is the result. When complement is present then haemolysis or bactericidal effects will be noticed, since the changes produced by sensitization have now permitted union with the complement. When leucocytes are present the union makes possible the phagocytosis of the antigen, and when the antibody is absorbed by the cells of the animal, anaphylactic sensitization occurs. In face of the simplicity of the "unitarian" theory the burden of proof of the multiple nature of antibodies would seem to fall on those who claim separate origin.

26. Experimental Epidemic Encephalitis in Rabbits.

KLING, DAVIDE, and LILJENQUIST (*Hygiea*, November 16th, 1921) make a further report (see EPITOME, November 26th, 1921, para. 518) on their experimental work in inducing typical epidemic encephalitis in rabbits by the intracerebral injection of material obtained from the brains, throats, and faeces of patients who had died or were suffering from typical epidemic encephalitis. In a few instances the rabbits died in a week or two after inoculation, but as a rule the disease lasted several weeks or months, and one of the rabbits did not die till seven months after inoculation. Even when rabbits were killed during the incubation period, and before the appearance of definite cerebral symptoms, marked changes in the brain, characteristic of typical epidemic encephalitis, were sometimes found. The authors suggest that the same events may occur in man, the disease existing in the brain but running an abortive and more or less symptom-free course. Like syphilis, epidemic encephalitis appears to run a capricious and, at times, seemingly inactive course in the central nervous system, and the duration of the disease may be one of weeks, months, and even years. The authors found the virus to pass a Berkefeld filter, to be invisible, refractory to culture, and glycerol resistant.

British Medical Association Lecture.

ON

SPECIFIC SENSITIVENESS AND ANAPHYLAXIS.

BY

H. H. DALE, C.B.E., M.D., F.R.S.,

OF THE DEPARTMENT OF BIOCHEMISTRY AND PHARMACOLOGY,
MEDICAL RESEARCH COUNCIL.

I have honoured me with an invitation to lecture to you on the pharmacological subject. I have never felt able to attach a rigid significance to those divisions which, for our convenience, we make in the body of medical science, and shall venture to assume that the form of your invitation implied that you were good enough to desire that I should speak on some subject in which my own work has given me a direct interest. I propose to devote my remarks to a subject which seems, at the moment, to have a great and increasing interest for workers in clinical medicine—namely, a group of specific idiosyncrasies, which definitely includes, among other cases, spasmodie asthma, and specific fever, and seems destined to extend its boundaries to include many cases of eczema, and, in the view of some enthusiasts, epilepsy, and various other conditions. The clinical study of these conditions, for which most general practitioners have daily opportunities, I can only approach as an interested outsider. Fortunately there are several recent and readily available publications dealing comprehensively with this side of the question. Dr. John Freeman lectured on the subject to the Royal Society of Medicine, Mr. Frank C. to a meeting analogous to this, and at the annual meeting of the British Medical Association last July illuminating discussions were opened by Sir Humphry Rolleston and Harold Barber. The clinical investigation of these conditions made rapid strides in the United States of America during the war, and the publications of Chandler Walker, Richet, and others abound in interesting detail. My object is to endeavour to put before you the conception as to the meaning of those phenomena to which experimental evidence now seems definitely to point.

For the experimental basis of any conception which we give of the form of these manifestations of specific sensitiveness or idiosyncrasy we must look to the investigation during the last fifteen years of the phenomenon known as anaphylaxis. I shall make no attempt at a review of the confused and in some ways overwhelming mass of literature which has accumulated round this phenomenon. I shall not even try to put before you the various theories as to its meaning, with the merits of evidence for and against them. I shall, quite briefly, put before you, and commend to your acceptance, the theory which alone seems to me adequate, secure in the conviction that it is the only one that can enable you to bring the facts of clinical experience into coherent relation with those of laboratory experiment. It is fair that I should state that there are still many who do not accept the view which I shall put forward; but I believe I shall do you a greater service by presenting one clear and consistent scheme, than I should by producing a confusion of rival theories.

The First Recognition of Anaphylaxis.

The first recognition of anaphylaxis as a definite phenomenon was due to Richet. He was working on the substance known as sea-anemones, which owe their stinging properties—a property which might seem almost peculiarly remote from the problems of general pathology and practical medicine, though you will note that the effect of the poison, in common experience, was to produce a reaction of an urticarial type, where normally inoculated by the thread-cells of the animal. Richet determined the toxic dose of a preparation for dogs, and, having given a subtoxic injection to a dog, he gave the same animal a second similar injection a few weeks later, with the effect of producing an immunity to the poison. The result, on the contrary, was an immediate and violent reaction, with swelling and irritation of the skin, vomiting, purging, hæmorrhage from the intestine, and profound collapse. As he was working with a substance which, in larger doses, produced a reaction of somewhat similar though less rapid type in the normal dog, Richet naturally supposed that the condition

which he had accidentally produced was an artificially lowered resistance to the natural poison, the direct opposite of immunity or prophylaxis, and he named the condition "anaphylaxis."

The True Meaning of the Phenomena.

The name "anaphylaxis" has persisted and has passed into general use in medical literature, though it soon became clear that the conception which gave rise to it was not altogether correct. Evidence quickly accumulated which showed that any perfectly harmless protein, provided that it came from a species other than that of the animal into which it was injected, also behaved as an acute poison when it was injected a second time into an animal which, some weeks previously, had received an injection of the same substance. This phenomenon, indeed, had been observed and incidentally recorded by Magendie as long ago as 1839, and by several observers in the intervening period. Only after Richet's work, however, was it systematically studied and recognized as a regularly recurring phenomenon. The symptoms produced by reinjection into an anaphylactic animal were found to be the same, whatever the protein to which it exhibited this abnormal sensitiveness, though they differed according to the species of animal used for the experiment. The guinea-pig, in which the phenomenon was practically rediscovered in America, was found to exhibit the condition with great regularity, and has been the subject of a large proportion of the experimental investigations.

Anaphylaxis, then, is not to be regarded as a weakened resistance to a natural poison; it is rather a condition produced by previous introduction into the system of a foreign protein, in which the same protein, but not any other, acts on subsequent injection as an acute poison, whether it has normally any poisonous properties or not.

The Relation of Anaphylaxis to Immunity.

Anaphylaxis, though superficially so different, soon proved to have many points in common with immunity. The condition, we may say with certainty, is due to the formation of some kind of antibody. In the guinea-pig the specific sensitiveness can be transferred to a fresh animal by injecting the blood or serum of one which has been made actively sensitive; there is a "passive anaphylaxis," due to the transfer of ready-formed antibody, and corresponding to passive immunity. But there are features of this passive anaphylaxis which seem, at first sight, paradoxical. It does not appear immediately, even when the serum containing the antibody is injected directly into the circulation. It is not perceptible until some six hours have elapsed, and not completely developed for twenty-four hours. We can understand why, after a first injection of a protein, a period of ten days or a fortnight must elapse before the animal becomes sensitive; as in the better known reactions of immunity, time is needed for the response leading to the formation of antibody. But when the antibody is ready formed, one would expect the condition which it produced to appear immediately after its injection into the blood, and to be then at a maximum.

There is another paradox. Not only the serum of an anaphylactic animal will convey anaphylaxis; that from an animal immunized against a foreign protein, by a series of properly spaced injections, will convey this passive anaphylaxis even more efficiently—that is, in a much smaller dose. If we take a rabbit and give it a series of injections of, say, egg albumen, its serum develops a precipitin—that is to say, it acquires the property of forming an obvious precipitate when mixed with egg albumen in very high dilutions. Now a very small dose of the serum of such a rabbit, injected into a normal guinea-pig, will make the latter within twenty-four hours acutely anaphylactic to the normally innocuous egg albumen. There are strong reasons for identifying the so-called precipitin with the anaphylactic antibody; yet the serum of a guinea-pig made actively sensitive to a protein forms no visible precipitate with that protein, while the animal whose serum has acquired a high precipitating quality for a protein is not anaphylactic to it, but immune.

As so often happens, these seeming contradictions probably provide the real clue to the nature of the phenomenon with which we are dealing. We studied the fate of the precipitating antibody, injected into a normal guinea-pig, during the twenty-four hours which elapsed before the animal became fully sensitive. He found that it rapidly disappeared from the blood, and that when sensitiveness was fully developed the antibody had nearly all vanished. If the

animal, which had thus become acutely sensitive to a foreign protein, received a further large injection of the serum containing precipitin for that protein, the immediate effect was not to enhance but to suppress the sensitiveness. Antibody freely circulating in the blood was therefore not sensitizing, but protective in action; the antibody must be somehow changed, or must be differently located, before it could render the animal sensitive.

A satisfactory interpretation of these facts would be provided by the supposition that the antibody must get out of the blood and into the living cells of the tissues before it can render the animal sensitive. On this supposition the occurrence in the living cell protoplasm of an aggregation of

FIG. 1.—Shows the specificity of the reaction. The plain muscle was taken from a guinea pig rendered sensitive to horse serum by an injection of 0.025 c.c.m., given fourteen days previously. The dose added to the bath were in each case 0.1 c.c.m., making a concentration of 1 in 2,500 of a sheep serum, B, cat serum, C, rabbit serum, D, dog serum, E, human serum, F, egg white, and finally of a horse serum (From the *Journal of Pharm. and Exp. Therap.*, iv, p. 214.)

favour, I must give some further details as to the nature of the poisonous action.

The Nature of the Symptoms.

I have said that, whatever the protein producing the condition, the picture of the anaphylactic poisoning is practically constant in the same species. In the different species the symptoms are superficially very dissimilar. When the protein is injected intravenously, the guinea-pig which is anaphylactic

FIG. 2.—A similar experiment, the guinea-pig being made sensitive to egg white by an injection of 0.1 c.c.m. twelve days previously. At A 0.5 c.c.m. horse serum, at B 0.1 c.c.m. egg white. (From the *Journal of Pharm. and Exp. Therap.*, iv, p. 189.)

to it dies in a few minutes, and in an extraordinarily dramatic manner, the cause of death being a tense contraction of the plain muscle surrounding the bronchioles, which in this species are small in diameter and provided with a rich and folded mucous membrane. The rabbit dies of right-sided heart failure, due to excessive resistance developed in the branches of the pulmonary artery. In the dog the central feature of the effect

poisoning of the endothelial wall of the blood capillaries. One or other of these effects predominates, and is locally prominent, according to the special conformation or liability of the tissues in the different species; but fundamentally the action is of the same kind in all. The view that we are dealing with one common type of poisoning, as exhibited by these different species, is confirmed by the observation that there is a whole group of natural poisons, partial cleavage products of proteins, formed by bacterial or other ferments, which produce these same pictures of intoxication, with the same striking differences, in the different species. Among such bodies I may mention the base known as histamine, a base easily derived from the amino-acid histidine, which is a constituent of almost all proteins.

Laidlaw and I some ten years ago described the intense activity of histamine, and drew attention to the fact that in each species it produced a picture of intoxication resembling that seen in the anaphylactic shock. This has led some observers to suggest that histamine

FIG. 3.—Shows that the reaction discriminates between the pure egg albumen of the hen and the duck. Guinea-pig sensitized with 1 mg. of pure hen albumen twenty-one days previously. No response to duck albumen. After the first effective dose of hen albumen the plain muscle is desensitized, and no longer responds to this substance, even in a ten-fold dose. (From the *Biochemical Journal*, xiii, p. 253.)

is actually formed in the anaphylactic animal, when the protein to which it has been sensitized is again injected. A suggestion of the part played by histamine in such phenomena appears again, as we shall see, in connexion with current views as to the nature of asthma. I have never been able to accept such a view of the events in the anaphylactic shock, or any other which attributes the symptoms to the formation of a poisonous product in the blood, and the action of this as the directly toxic agent. All such views are, for me, excluded by the simple fact that simultaneous injection of the antigen and the antibody concerned in the anaphylactic reaction, so that they meet in the blood, has no perceptible effect of any kind. So far as I am able to judge, the simple view that the anaphylactic condition is due to location of the antibody in the cells of the vital tissues, where its reaction with the antigen is the cause of the symptoms, suffices to account for all the phenomena which can with certainty be regarded as anaphylactic.

Direct Evidence of Cellular Sensitization.

Returning to a consideration of this simple conception, we have seen that a characteristic feature of the anaphylactic reaction, in the guinea-pig especially, is stimulation of plain

FIG. 4.—Shows that the reaction discriminates between individual proteins of the same serum. The guinea-pig was sensitized with 1 mg. of the egg albumen of horse serum thirteen days previously. At A and B 1 mg. and 10 mg. of the pseudoglobulin of horse serum were added to the bath without effect; at C 10 mg. of the egg albumen of the same serum were added. (From the *Biochemical Journal*, x, p. 422.)

muscle from a guinea-pig rendered passively sensitive behaves in the same way. We ought further to find that the same antibody as conferred the sensitiveness, if present in excess in the fluid surrounding the plain muscle, will protect it from the protein to which it has been made sensitive, so that it no longer responds. In other words, we should be able to make *in vitro* artificial combinations corresponding to the conditions of active and passive anaphylaxis and of true immunity.

There is another condition, which we ought to be able to illustrate in such experiments, and which I want clearly to differentiate from immunity—namely, the condition which

is somewhat clumsily been called "antianaphylaxis," and which I should prefer to call "desensitization." When a sensitive guinea-pig is given a sufficient dose of the antigen to cause symptoms, but not death, especially if the antigen is slowly introduced, so that the dose can be relatively large without killing the animal, it is found on recovery to have lost its sensitiveness, and to remain normally insensitive for a week or so. The antibody which its cells contained has been shed up; more must be formed and fixed to the cells before the guinea-pig is again anaphylactic. Contrast this with the condition which I have called "true immunity," in which plenty of antibody is present, but in such excess in the body fluids as to catch the antigen and put it out of action before it can reach the sensitive cells.

Now it is very simple to demonstrate all these phenomena on a slip of plain muscle taken from the guinea-pig after death. This is carefully freed from all traces of blood or serum by perfusing Ringer's solution through its vessels, and it is then suspended in a small volume—100 c.cm. or so—of clean Ringer's solution, kept at body temperature, and saturated with oxygen. To this bath the antigen can be added, and the response of the strip of plain muscle recorded by fixing one end and attaching the other to a light lever, writing on a slowly revolving drum. The tracings show the ease with which the various phenomena can be demonstrated; they are taken from a series of papers which I have published since 1913. (See Figs. 1 to 5.)

You will agree, I hope, that these figures give direct support to the conception that anaphylaxis is due to sensitization of the cells by the presence in them of the precipitating antibody, excess of which in the surrounding fluid protects the sensitive cells and constitutes an immunity.

Non-specific Sensitiveness and Non-specific Desensitization.

So far we have been dealing with the experimental phenomenon of anaphylaxis as seen in the laboratory, and, before leaving it, there is one other point which I want to make clear, as it has some bearing on our further discussion. We have seen that the anaphylactic sensitiveness is highly specific, discriminating between similar proteins from different species, and even between different proteins from the same species. But the animal which is highly anaphylactic, whatever the protein to which it has been made sensitive, shows a so some degree of enhanced sensitiveness to naturally poisonous substances, having a type of action resembling that seen in the true anaphylactic response.

The upholders of the alternative theory, which supposes that the anaphylactic shock depends on the formation of a poison in the blood, have shown that normal guinea-pig's serum, when treated with various colloids and suspensions, acquires a toxicity of such a kind that it kills a normal guinea-pig with symptoms more or less closely resembling those of the anaphylactic shock. To such a toxic serum the anaphylactic guinea-pig usually exhibits an abnormal sensitiveness, so that the cell protoplasm would appear to have acquired a more general instability, an increased liability to this kind of toxic disturbance, in addition to its highly specific idiosyncrasy of reaction to one, normally harmless, protein in particular.

In this connexion also mention should be made of another point of contact between true anaphylaxis and non-specific intoxications. We have seen that the anaphylactic guinea-pig, which recovers from the effects of reinjection, is desensitized for a week or so. An anaphylactic guinea-pig, which recovers from a non-fatal dose of one of the natural poisons producing similar symptoms, is found to be less sensitive to its specific antigen than another, similarly sensitized, but not treated with the non-specific poison. The full sensitiveness is, in this instance, recovered in twenty-four hours or so, and there is no evidence as to whether the

temporary loss of sensitiveness is due to destruction of the body from the cells, or to formation of some substance which inhibits aggregation in the protoplasm. The latter is worthy of note, as having its parallel in a human treatment, as we shall see later.

Anaphylaxis in Man.

Turning now to a more practical aspect of the problem, we have to inquire what bearing these phenomena have on the treatment of guinea-pigs and other animals in the laboratory, and on the conditions seen in man. The first and most important question is to the effects of injecting horse serum in patients. You will be familiar with the fatal results of the proportion of patients, as the result of a fatal reaction to horse serum, exhibit, after an interval of a few days, a reaction which has many features suggesting anaphylaxis, dealing with an anaphylactic phenomenon. The symptoms point clearly to an injury of capillary walls, leading to urticaria, swelling or pain in the face, sometimes facial oedema, accompanied by constriction of the airways. The latent period of some eight to ten days is suggestive; it is the interval needed in the human case for the appearance of the anaphylactic condition. I suspect that in this interval an antibody is formed, and located in the tissue cells the sensitiveness gradually rises, till reaction with some of the original dose of horse-serum protein causes

symptoms. The susceptibility is enhanced when we consider a further injection in a patient at an interval of months. The phenomena have a certain certainty of production, but a certain number of patients receiving such a second dose have a reaction of a more anaphylactic type. The reaction is immediate in the neighborhood of the hypodermic injection, and in a short time a general constitutional reaction of a severity greater than normal severity of the glottis may be produced, or, in a more severe case, be a dangerous condition. In a case where such a second injection was made intravenously, the result has been rapidly fatal. It is quite obviously the case that in other animals, having been sensitized, produce a typical anaphylactic reaction, though there can be little doubt that the nature of the phenomenon we are dealing with is

FIG. 5.—Plain muscle from a guinea-pig which has been rendered immune to horse serum, showing that, when washed free from the protective excess of antibody in the blood, it is sensitive, like that from the anaphylactic animal. At a, 0.5 c.cm. of horse serum was added to the bath; at b, 0.5 c.cm. of sheep serum. (From the *Journal of Pharm. and Exp. Therap.*, iv, p. 191.)

clear that the anaphylactic condition is not with nothing like the fatal regularity with which it is seen in some of the animals used in the laboratory. It is reason to suspect its presence, a small injection of the serum should reveal it without symptoms, and at the same time begin the process, which must be completed by careful intravenous doses before a large intravenous dose can be undertaken with safety. When we begin to consider the after the first year of the late war, practically all the men in our armies received an injection of horse serum, and that a large number must have received treatment by an immune horse serum or another, the paucity, in relation to the reports of dangerous or fatal anaphylactic reactions, indicate that such sensitization in man is the exception rather than the rule.

Indeed, of the total number of fatalities resulting from injecting horse serum into man, a small proportion have occurred after injections in patients who have never received serum before—into patients, say, who had a natural sensitiveness to horse serum, but whose intensity but seldom appearing as the result of an injection. A large proportion of such cases have occurred in subjects of asthma: but I am not sure that data which would entitle us to connect them with an asthma due to horse sensitiveness. It is not so surprising to find such a connection. This leads us to another part of our subject.

* Records were also exhibited, which will be published shortly by Dalo, showing that the anaphylactic plain muscle can be protected from the antigen by adding to the saline bath an excess of antigen, which was used to sensitize it previously.

leaving the question of serum sickness I should like to mention one further point of some theoretical interest. There are numerous records of more than one rash following a single injection of horse serum, the rashes following one another with an interval of a few days. I have searched and inquired, but have found no record of more than three such distinct rashes in one patient following a single injection. Now, there are three distinct proteins in horse serum, and it is possible in the guinea-pig to produce a separate sensitiveness to each; and these do not develop simultaneously, but at different intervals from the primary injection.

Naturally Occurring Specific Sensitiveness ("Toxic Idiopathies").

Turning now to the question of the different types of specific sensitiveness, which appear to be inborn or to develop spontaneously in some human subjects, the case of hay fever or hay asthma seems fairly clear. It is common ground that we have, in this case, a cellular sensitiveness to the proteins of certain pollens which are easily borne on the wind. In this country grass pollens are chiefly responsible; in the United States they have a second outbreak of a similar condition in the autumn, due to the pollen of a composite, the ragweed, which is very abundant there. The work of Noon, Freeman, and others has shown that the sensitiveness is not restricted to the conjunctiva and respiratory mucosa; the reaction occurs in these regions especially, because the proteins of the pollen can there easily reach the sensitive cells. A typical urticarial wheal is formed on the skin, however, if the pollen is applied to a lightly scarified area; and Freeman, by getting a subject of hay fever to ingest grass pollen, produced in him a vigorous diarrhoea. The skin test can be used to discover the species of pollen to which the sensitiveness and the attacks are due.

Very much on the same footing are the numerous cases of asthma which, by investigations in recent years, have been proved to be excited by the inhalation of minute quantities of material originating from some particular species of animal—horse, cat, or dog being, apparently, the commonest culprits. The substances exciting reactions of this type are mostly particles of epidermal origin—hair or scurf from the skin—and the patients give a specific skin reaction to proteins extracted from the material responsible and applied to a minute, very superficial cut. Usually, but not always, the patient sensitive to the epidermal structures shows also a sensitiveness to the blood serum of the same species. It is hardly a matter for surprise, therefore, that there are cases on record in which asthmatic patients have exhibited a fatal sensitiveness to horse serum, injected with a therapeutic or prophylactic aim. Many cases have been brought to light in which asthma, coming on at night, was associated with a sensitiveness to chicken feathers, and disappeared when a pillow stuffed with horsehair or vegetable fibre was substituted for a feather pillow.

Now, cases of this kind present many points of close similarity to the condition of artificial sensitiveness or experimental anaphylaxis. An objection to their identification has been raised on the ground that the so-called natural idiosyncrasies cannot be passively transmitted. I admit that such an objection would be fatal if we were to adopt the humoral theory of anaphylaxis, attributing the condition to the presence of an antibody in the blood, with which the antigen there reacts. But on the theory which I have commended to you, which attributes sensitiveness to an antibody present in the cells, the objection has little weight. It is true that anaphylaxis can be transferred from the anaphylactic to a normal guinea-pig, at a time when the anaphylactic condition is newly developed. But after an interval of months from the primary injection, though the sensitiveness is still acute, passive transfer often fails; the antibody has practically disappeared from the blood. We have only to regard these cases of human sensitiveness as extreme examples of this condition—and the sensitiveness is, indeed, often of an extreme order—in which the antibody, if it ever was in the blood, has usually become located exclusively in the cells, to bring the two kinds of phenomena fully into line. There are, moreover, a few cases on record in which the blood was by no means free from antibody. Ramirez records a case in which, after receiving a transfusion of blood from a fellow patient, who happened to be a subject of horse-sensitiveness, a patient was seized with asthma, for the first time in his life, on going for a drive in a horse-drawn carriage during his convalescence.

When attacks of asthma or urticaria, or both, are excited

by the ingestion of certain articles of animal or vegetable food, another difficulty of explanation presents itself. The cases present similar phenomena of specificity, and respond as well to the 'diagnostic' skin reaction as the former class. But it is 'contrary to experience in experiments' on anaphylaxis that the symptoms should be excited when the protein is swallowed, and, therefore, has to run the gamut of the digestive juices before absorption. I believe the fact to be that we do not, by experimental procedures, succeed in producing such extreme sensitiveness as that which appears in certain human patients. Even the minute traces of unbroken protein which pass the alimentary mucosa, possibly owing to some fault of digestion or absorption, seem sufficient, if they are of the specific kind responsible for the condition, to cause an outbreak of urticaria or an attack of asthma. Sensitiveness to the proteins of certain molluscs and crustaceans, or of certain fruits, such as the strawberry, is not uncommon. They cause little trouble, since the patient learns that he cannot tolerate these foods, and avoids them. When the sensitiveness is directed to a protein occurring in some common article of diet, such as wheat, egg, potato, or milk, the cause of the condition is often not identified by the patient, and requires a skin test for its detection. Even when the diagnosis is complete, treatment by elimination of the offending protein from the diet may present great practical difficulty.

Other Features Concerned in Asthma and Similar Conditions.

Time alone can show what proportion of the cases of spasmodic asthma and urticaria will ultimately be referable to this type. At present the tendency is for the proportion to increase, as investigators gain experience in the application of the specific tests, and have a growing range of animal and vegetable proteins under suspicion and available for use. There are other factors, however, which are generally credited with importance, and which are often regarded as incompatible with the conception of the condition as due to sensitiveness to a foreign protein.

One such factor is heredity; but it is clear, from some interesting family trees published by Freeman, that the inheritance is not of sensitiveness to a particular protein, or even of a certain type of reaction, but of the tendency to acquire some kind of idiosyncrasy for foreign proteins. A father subject to hay fever may have among his children one suffering from horse-asthma and another from some idiosyncrasy to a particular food, and so on. If the inheritance is simply of the tendency to respond, by forming cellular antibody, to some chance parenteral introduction of a trace of foreign protein, the hereditary tendency is in no way inconsistent with the conception which we have been discussing.

Another factor in the causation of asthma or hay fever which has also been regarded as inconsistent with the theory of sensitization by foreign protein is that of neurosis. Many cases are on record in which the sight, or even the mental image of the supposed source of the sensitizing protein, without any possibility of its actual presence, has been sufficient to induce an attack—the sight of an artificial rose, a film at the picture palace representing hay-making, or, in a case recorded by Freeman, a vivid description of a field of mustard in flower. I have already disclaimed any experience of clinical matters, but as an experimental worker, who has read something of Pavlov's more recent work, I find it difficult to believe that any real incompatibility exists between such phenomena and the view that the condition has its origin in specific sensitization to foreign protein. We know from Pavlov's work that in a dog, an animal of relatively simple psychical development, it is possible, by daily association of a sound or a skin stimulus with food or acid in the mouth, to produce a new psychical reflex, so that the sounding of the note or the stimulation of the prescribed skin area now suffices by itself to evoke a secretion of saliva. I do not think it is difficult along such lines to suppose that a man who has become sensitive to rose pollen, and has had repeated experience of an association between the presence of roses and suffocating constriction of his bronchial tubes, might ultimately develop a new reflex, connecting the visual image of roses with the nervous control of the bronchioles, so that the sight of an artificial rose would eventually suffice to excite an attack of asthma.

There are, I gather, other cases of asthma in which the attacks seem to be excited by some non-specific chemical stimulus—in which, for example, a digestive disturbance,

a mild enteritis, however produced, is sufficient to produce an attack. It would appear that in such cases the absorption of poisonous cleavage-products of proteins may be the exciting cause, and even histamine has been held by some writers to be responsible. If you have in mind what I stated, in dealing with experimental anaphylaxis, concerning the generally enhanced sensitiveness of the anaphylactic animal to poisons of this type, you will find no difficulty in reconciling the occurrence of such attacks with a specific, anaphylactic origin of the asthmatic condition, in the patient in whom they occur. Nor should the evidence brought forward by Auld and others, as to the improvement of such patients under treatment with small injections of poisonous protein derivatives, such as Witte's peptone, present much difficulty of interpretation, if you remember my statement that the anaphylactic guinea-pig can be partially desensitized by a similar non-specific intoxication.

I am by no means suggesting that every case of so-called asthma is of the anaphylactic type. Even if the so-called cardiac asthma and renal dyspnoea are excluded, I imagine that there are many cases in which the symptoms are asthmatic, but which have a different origin altogether. When the question is raised of sensitization to the proteins of infecting organisms, the distinction between a primary toxic action of their products and an anaphylactic reaction to their proteins becomes difficult to draw. Especially is this the case with an infection of the respiratory passages themselves. There seem to be some clear cases, however, of infection at a distant site, causing, not a local trouble, but a genuine general anaphylactic reaction. But the discussion of the relation of anaphylaxis to bacterial proteins, full of suggestion though it is for a rational conception of the genesis of certain chronic morbid conditions, would lead us into such inadequately charted waters that I shall not attempt the role of pilot. My object has been to provide, from the experimental side, a more definite conception of the nature of those conditions in which sensitization to foreign proteins is clearly established; such a conception as may help to focus ideas, to stimulate observation, and even to rationalize treatment.

A British Medical Association Lecture

ON THE

DIAGNOSIS AND TREATMENT OF INTRATHECAL
TUMOURS OF THE SPINAL CORD.*

BY

WILLIAM THORBURN, K.B.E., C.B., C.M.G., F.R.C.S.,

EMERITUS PROFESSOR OF CLINICAL SURGERY, MANCHESTER UNIVERSITY;
CONSULTING SURGEON, MANCHESTER ROYAL INFIRMARY.

In this lecture I shall not endeavour to advance any original ideas, but will present certain aspects of an important topic which, although they are familiar to the neurologist, are, I fear, not so well known as they ought to be to the general body of the profession. The subject is important because we have in the treatment of intrathecal tumours of the spinal cord one of the most, if not the most, reliable developments of the surgery of the nervous system, and yet I am convinced that in this country many cases which could be readily and almost dramatically cured are allowed to pass without recognition or radical treatment and to run unaided their inevitable course to death.

I propose to illustrate my remarks by showing two patients, both operated upon sufficiently long ago to demonstrate what may reasonably be called "end results." The first will serve to illustrate all the salient points of an intrathecal tumour; the second is one of a more obscure condition liable to be confused therewith.

H. B., a motor driver, aged 43, came under my observation in the Manchester Royal Infirmary when I was asked to see him by my friend, the first point which I must not come directly before the surgeon, it will quite properly lie with the general

practitioner and the physician to make the preliminary diagnosis, without which nothing further can be done.

The patient, whose complaint may be briefly described as "paraplegia," gave a clinical history of the utmost importance. About the end of 1918, while in an army hospital with an attack alleged to be one of influenza, he noticed what is described as an indefinite pain about and just below the left costal margin. At first this pain was felt only in the morning, and it passed away throughout the day, but it tended gradually to become more constant. In March of 1919, when demobilized, he had no great amount of pain, but suffered a little from what he and his advisers called lumbago. He was, however, able to return to civil work and to continue therewith until October. During this period he noticed a gradually increasing weakness of the left lower limb, which at first used occasionally to "give" a little, and which later began to "drag." In the autumn of 1919 the right leg also began to show similar symptoms, and he then had to give up his work, although still able to walk about with the aid of a stick. In the month of January, 1920, he became rapidly weaker, and in the first days of February he was entirely confined to bed. From that time until I saw him in March he was in hospital and only growing feebler.

I have dwelt in detail upon this clinical history for reasons to which I shall return directly, but we may now turn to his condition as first seen.

He could not stand or walk unless supported. The right leg was very weak; the left could not be moved in the bed. When assisted he attempted to walk, but did so with an extremely spastic gait, more marked on the left side. There was no marked atrophy of the limbs, but the left was thinner than the right. As regards anaesthesia, he presented fairly good appreciation and localization of contact throughout, although there was a little delay in response. The appreciation of heat and cold and the sense of pain were lost in both lower limbs, and thence upwards to a level of about 2 in. above the umbilicus. Knee-jerk was exaggerated on both sides, and he had marked ankle clonus, especially on the left; the plantar reaction was extensor; the lower abdominal skin reflexes and the cremasteric reflexes were very sluggish. Bladder and rectum showed no abnormality. Pain was of the girdle type, running round immediately above the umbilicus, although in the early stages it had been assigned to a higher level; it was sufficiently severe to require a nightly dose of opium.

So far, then, we have a sufficiently typical case of a transverse lesion of the spinal cord more advanced on the left side, but on a very slight consideration of the symptoms and onset, we can go much further and recognize with almost absolute certainty an intrathecal tumour which may readily and most hopefully be removed—a diagnosis founded on both negative and positive indications.

About traumatic lesions we need not trouble. I have seen several cases of haemorrhage into the lower dorsal region of the cord, generally occurring in boys or young men and often after bathing in cold water, but in such, as in trauma, the onset is acute. Tuberculous disease of the spine is excluded by the absence of any evidence of bone disease either clinical or radiographic, and by the very slow onset; in this connexion I may say that local tenderness on tapping the spinous processes, and even local kyphosis may be present in the case of intradural growths, and that such symptoms must not be taken as excluding the presence of such growths, but here this possible source of error had not arisen. For similar reasons it is not at all probable that we have a growth—generally malignant—of the vertebrae themselves; the pain is not the intense pain of "paraplegia dolorosa" met with in such cases, and, while vertebral growths are generally secondary, there is here no indication of any primary growth elsewhere. Syphilis is excluded, so far as exclusion is possible, by the total absence of any indication of that disease, and by the fact that the cerebro-spinal fluid gave a negative Wassermann reaction. Growths, tuberculous masses, and cysts within the cord itself are all comparatively rare, especially in the lower dorsal region, and are not as a rule accompanied by pain. Cysts, such as hydatid cysts, in the meninges would, of course, produce the same symptoms as true tumours, but their treatment is identical. Of a remaining possible source of error I shall speak in connexion with our second case.

So much may be said for the negative side of our diagnosis. On the positive side we have a very strong argument. The essential feature of the clinical history was, as we have seen, pain long precedent to the paraplegia, of varying intensity and associated with remissions, while it was not localized in the back, but extended vaguely along one or more spinal segments. Such pains are almost invariably present as an early symptom of intrathecal tumours; I have traced back their history to as long as two years before any paraplegic phenomena were noted, and I have known them to be in abeyance for many months. They may or may not be associated with paraesthesiae or with a certain amount of anaesthesia. They may be bilateral or, as in the early stages of

* Delivered to the Birmingham Branch, November 17th, 1921.

this case, unilateral. Of somewhat vague nature, they are not often in themselves diagnostic until other symptoms supervene. They are generally described and treated as "rheumatic," or they may be regarded as due to visceral disease, as in one case in which a most eminent surgeon had advised operation upon the gall bladder in a man from whom I removed an intraspinal growth. Themselves, therefore, almost useless as a guide, they are of the utmost value when other medullary symptoms have developed, and it follows as a matter of course that every case of such radiating pain demands a most careful and, if necessary, a repeated search for indications of a transverse lesion of the cord, which may, as in our patient, approach most insidiously, and which show a strong tendency to be at first unilateral only.

Our diagnosis in the present case being, in my opinion, a matter of almost absolute certainty, it remained only to localize the level of and to remove the growth. The localization of the level demands, first, an accurate examination to ascertain the highest level of sensory or motor phenomena; secondly, a knowledge of the distribution of the spinal segments; thirdly, a recognition of the relation of these segments to the spinous processes; and fourthly, a correct enumeration of the processes themselves. It is doubtless due to a want of appreciation of these anatomical difficulties that many errors have occurred, and that the tumour has been missed through its having been sought too low down.

With regard to the appreciation of the highest level of symptoms it is not sufficient to accept the upper limit of what I may call "gross anaesthesia." The line of limitation is often very ill defined and only careful and repeated examination will enable us to determine it. In the present case a casual examination might readily have limited the level to a point below the umbilicus, whereas greater care showed some sensory loss as high as two inches above that landmark; pain had, indeed, been felt at a still higher level, but the overlap of segments causes pain to radiate far beyond the obvious anatomical distribution of the affected nerve and hence the ninth dorsal segment was regarded as the true level of the lesion. The peripheral distribution of the various spinal segments is now well recognized, and its consideration at this date would be merely a historical discussion into which I do not propose to enter, more especially as, with my old teacher James Ross, I may perhaps claim to have laid the basis upon which it rests. Moreover, in the case of the trunk, it is a peculiarly simple problem and the great majority of intrathecal tumours lie below the brachial and above the lumbar enlargement.

The relation of the affected segment to the spinous processes which are our guide to the site of operation is variable within somewhat wide limits, so that the operation must be sufficiently extensive to allow for individual differences. In the region with which we are now dealing the segment is generally about two vertebrae higher than the spinous process which bears the same number, so that for our ninth dorsal segment the centre of the incision will be at or even a little above the seventh dorsal spine, which again corresponds to the body of the eighth dorsal vertebra. Again, the determination on the operating table of the spine desired as a landmark is often far more difficult than might be supposed, especially in a stout or deformed person, and it may be necessary to find it beforehand by means of a radiogram with an indicator fixed to the skin, or even, as in one of my cases, by previously imbedding a piece of wire at the region required and then checking it by a radiogram.

In the case which we are now considering the operation, with the details of which I do not propose to trouble you, was performed on March 23rd, 1920, or, say, twenty months ago. The laminae of the seventh, eighth, and ninth dorsal vertebrae were cut across with the saw, the ligaments between the sixth and seventh divided with scissors, and the flap thus made turned downwards. There was at once observed an obvious fullness of the dura mater, which was laid open. The spinal cord was found to be pushed backwards and to the right, and a tumour was exposed to the left of and in front of it. One of the spinal roots, presumed to be the ninth dorsal, lay across its lower pole, and was divided to allow of the cord being gently drawn still further to the right, when there was fully exposed a firm, deeply red, encapsulated mass, which proved to be 3 cm. long, 1.5 cm. wide at its lower end, and very much of the size and shape of the terminal phalanx of the index finger. This was most readily shelled out, its attachments being, as is usual, quite loose. The actual seat of origin of the growth could not be determined owing to the very lightness of these attachments,

which almost give the impression that the tumour is lying free in the meningeal space; moreover, very little bleeding follows the blunt separation of the connecting bands. In structure the tumour was described by the pathological department as a "fibroma of rather cellular and vascular type."

Such an operation may be regarded as typical, except that it is more difficult in stout patients to turn down spines, laminae, and their connexions as a continuous osteoplastic flap. On the other hand, in this case the anterior position of the growth and its rather unusually large size rendered necessary a good deal of traction on the already markedly displaced cord. I must, however, again insist on the readiness with which these growths can be enucleated, those which are situated a little further back upon the cord almost giving the impression that, if the patient were rolled over, they would fall out as—to use a war-time illustration—a shrapnel bullet might fall out of a mass of granulation tissue.

The rather unusual difficulty in shelling out the tumour in the present case explains the fact that for a short period the patient had aggravated symptoms. For the first four days anaesthesia was a little deeper than before operation, but sensation to heat and cold then began to return and was rapidly followed by return of sensation to pain. Urine was retained and the catheter was required for the first eight days after operation, while he had a mild attack of cystitis, which quickly passed away. Return of motor power was more gradual but perfectly steady. On the twenty-eighth day both legs were quite movable in bed, the right being more so, but both still felt stiff; the right knee-jerk presented no exaggeration, the left slight only; the plantar response on both sides was an extension followed by flexion. At the end of six weeks he could walk about the ward with a stick and was able to go home. A month later the aid of the stick was dispensed with. Examination of his condition to-day will show that from a subjective point of view he is perfectly healthy and that the only peculiarities which can be detected are a faint linear scar upon the back and a slight irritability of the knee-jerks.

It remains to consider, as in all cases of tumour removal, what are the prospects as regards recurrence. Into the difficult question of the pathological nature of these intrathecal growths I do not propose to enter. Probably all arise from dura, arachnoid, or pia mater. Among my own cases I have had various descriptions from pathologists, such as haemangioma, lymphangioma, endothelioma, and fibroma, occasionally also sarcoma; far more extensive investigations have been made from *post-mortem* examinations, and many operators have recorded psammomata, which, curiously enough, I have not met with, or at least not recognized; hydatid cysts are not by any means unknown; but again I have not seen such. The important practical point is that I know of no case of recurrence even in patients operated upon many years ago. I have met with one case only of infiltrating sarcoma, which invaded the conus medullaris and the cauda equina for many inches, and in which excision was out of the question; I have met with one case of long standing in which functional recovery after excision was very imperfect; I have had one case in which, on clinical grounds, I advised operation, but the misreading of a radiogram (now many years ago) was taken to show a large ossifying sarcoma—nothing was done, and the patient died, when the autopsy revealed a condition quite similar to that of H. H. On the other hand, I have had at least a score of cases in which the operation was as simple and the results as satisfactory as in the one before you. The operation mortality is nil, as I have found it to be in all cases of laminectomy for exploration, rhizotomy, spinal drainage, and the like. But I regret to say that I know of a good many cases in which operation has been refused and death ensued. It is my earnest hope, gentlemen, that such cases will become more rare than they now are, and that in all which are doubtful the safe and simple expedient of exploration will be adopted.

And now I will ask you to turn to my second patient, whose case illustrates some difficulties of diagnosis and some of the advantages of exploring when in doubt.

R. C., aged 22, consulted me on December 6th, 1920. From boyhood he appears to have suffered from vesical catarrh for which I have found no cause or explanation and from which he had no practical inconvenience. In the year 1917 he had an attack of fever of unknown nature while on naval service in Cuba; other-

he has been perfectly healthy. Nine weeks before I saw him and a disagreeable sensation which he describes "as if his toes were tied together." His legs then became weak and stiff and he was unable properly to control their movements. He had a little trouble on bending strongly to the left and appeared to have some tenderness of the left kidney, but these symptoms were so slight that he was quite doubtful. Incompletely paraplegic, he had great increasing difficulty in moving about the room with the aid of sticks. Anaesthesia, which was nowhere complete, extended to a wide margin a short distance above Poupart's ligament. Knee-jerk and ankle clonus were markedly exaggerated. There was no difficulty in commencing to micturate but no retention of urine.

A week later when he came into hospital paraplegia was almost complete; he could neither stand nor walk. Anaesthesia was well marked and extended nearly to the waist line. The knee-jerk and the ankle clonus were more marked on the left side; the plantar reactions were flexor. Three weeks in hospital were devoted to the attempt to define symptoms a little more closely, to look for any sign of improvement from complete rest, and to search for any of the more common causes of transverse lesion of the cord. We found no evidence of tubercle or other bone disease, there was no indication of syphilis, and the Wassermann reaction to the cerebro-spinal fluid was negative. There was equally no evidence of past or present gonorrhoea; the urine contained small quantities of pus, but no organisms were discovered. Anaesthesia varied a good deal in its intensity and slightly in its upper limit, sensation was normal above the line of the umbilicus. Paraplegia increased, so that he could not move his lower limbs in the bed.

Here, then, we have a clinical picture which I may describe as the blurred image of an intrathecal tumour. Anaesthesia did not be recorded in diagrams as it was vague and unhelpful but with a tendency to extend upwards. Paraplegia was steadily increasing in intensity. The reflexes were those of a transverse lesion except for the plantar reaction. There was no longer any pain, and pain had always been of the slightest. Such a condition reminds us of some of the cases described by Horsley as "chronic spinal meningitis" and by Spiller as "circumscribed serous spinal meningitis." The general outline as given by Horsley resembles that of a tumour of the cord, but pain is less definitely localized and there are often widely spread hyperaesthetic areas; anaesthesia is incomplete and without dissociation; paralysis comes on as a widely spread weakness, often unilateral; there are no vasomotor symptoms; the patients are almost always adults, and the upper level of anaesthesia is usually mid-dorsal. Some of Horsley's cases were regarded as syphilitic, several as due to recent gonorrhoea, and others were assigned to influenza.

Operating on 21 cases of this type which had been originally regarded as tumours Horsley found excess of cerebro-spinal fluid, thickening of the arachnoid, "matting of nerve roots," and compression of the cord. He opened the dura mater, irrigated with strong solutions of mercuric chloride, and left the theca open for drainage. The good results which he obtained he compares to those which follow laparotomy in tuberculous peritonitis.¹

When this description appeared I had already met with a few similar cases—notably one in which I thought that the symptoms of a tumour of the cauda equina were unequivocal, but in which I found only thickening of the dura mater with very large quantities of cerebro-spinal fluid; after this had been opened up and drained recovery was to my surprise complete, but I fear that I then dismissed the matter from my mind as an unexplained error in diagnosis.

The case of R. C. appeared to me to be most probably of similar nature, and the source of infection as vesical or renal, and I decided upon an exploratory operation, which was performed on December 28th, 1920. The sixth, seventh, eighth, and ninth dorsal laminae were totally removed, it being difficult to do an osteoplastic operation on account of the rather free haemorrhage and depth of the wound rendering unsafe the use of the saw. In the centre of the exposed area of the theca it was at once obvious that there was some change; above this point pulsation was very marked; below it ceased entirely and abruptly; there was also an appearance of a slight constriction. An incision four inches long was then made into the dura from below upwards, and cerebro-spinal fluid only began to flow when the incision was carried above the point noted; above this point the flow was very free, from which I concluded that there was here some slight adhesion of the meninges, although there was no visible cicatrix. As the patient's condition was giving a good deal of anxiety to the anesthetist, while free bleeding and escape of cerebro-spinal fluid obscured the view, I decided to complete the exploration a few days later. Four days afterwards, when the wound was reopened, there gushed out from its deeper part at least two or three ounces of cerebro-

spinal fluid, but nothing farther was discovered after a most careful search, including the anterior aspect of the cord, and the wound was again closed, the dura mater being left freely open.

For four or five days after this second operation there was a good deal of pain; at the end of a week the lower limbs could be moved, and at the end of a fortnight were freely movable, while sensation was distinct everywhere, although still somewhat wanting in acuteness. On account of the amount of injury inflicted upon the bones of the spine I kept the patient in bed longer than usual, but after two months he could walk, although with difficulty. He can, as you will see, now go about quite easily, and he says that the only thing that he cannot do is to run; he is, as he will tell you, not conscious of any physical defect, although his knee-jerks are still exaggerated, and probably always will be so. His old vesical condition is naturally not affected by the operation, and I am hoping that it may now be found possible to do something to correct it.

I have brought this case before you more particularly to illustrate three points—namely, first, the great importance of exploring doubtful cases of transverse lesion of the cord—that is to say, all cases which are not obviously hopeless; secondly, that you are more likely to do good than harm should a diagnosis of a thecal tumour prove incorrect; and thirdly, because I hold that there is a strong probability that many early cases of transverse myelitis may be arrested and cured by incision and drainage of the dura mater—a possibility fully in accord with the view that such myelitis is often due to infection spreading along the spinal nerves and then necessarily crossing the meninges and the intradural space before the cord itself is attacked. If this view of the causation of transverse myelitis be correct—and there is strong evidence in its favour—we may then hope to arrest the infection in its course and to save the cord before it is irretrievably damaged. When once a portion of the cord has been converted into a cicatrix there is nothing to be done, but if we can arrest infection at its onset it is reasonable to hope that the patient may be saved. In all other regions of the body we aim at the drainage of infections at the earliest possible moment; in this, the most vulnerable of all regions, we can only hope to save by exceptionally early drainage of even the mildest of infections. And, before leaving this side-issue of the present address, I may add that I think the infections usually derive from the urinary organs—a view in accord with the cases which I have myself seen, with the tendency of transverse myelitis to attack the levels connected with the kidney, and with the fully recognized tendency of the kidney itself to collect and harbour organisms of all types.

Gentlemen, I have, with the exception of a single reference to the great pioneer of the surgery of the nervous system, given you only the results of personal experience, and I am only too well aware that as surgeon to a general hospital I have not the advantage of those practising in hospitals specially devoted to the diseases of the nervous system. For this reason I cannot bring before you extensive statistics, nor can I hope to do more than help to throw a very little light upon neurological questions. But the more obscure and limited field of to-day becomes the commonplace of tomorrow, and I am convinced that the search for and the recognition of cases such as I have described to you will result in the discovery and the salvation of many which are now lost. The neurologist and the surgeon are fully prepared to deal with them, although the neurological physician perhaps hardly realizes the safety of laminectomy. It is therefore now necessary only to make such cases more widely known to the great body of the profession in order that we may realize an advance in treatment similar to that which has occurred in other branches of practice.

REFERENCE.

¹ BRITISH MEDICAL JOURNAL, February 27th, 1920.

THE International Grenfell Association now has five hospitals established on the shores of Newfoundland and Western Labrador; an orphanage was built at St. Anthony, on the north coast of Newfoundland, last summer.

THE Federation of the American Society of Experimental Biology, composed of five societies, held its annual meeting at New Haven, U.S.A., from December 28th to 30th, under the auspices of Yale University. Dr. J. J. R. McLeod, of the University of Toronto, president of the American Physiological Society, was president. The annual meeting of the American Association of Anatomists was held at the same time.

THE VALUE OF FREEDOM AND EXERCISE AFTER OPERATIONS.

BY

R. P. ROWLANDS, M.S., F.R.C.S.,

SURGEON TO GUY'S HOSPITAL, LONDON.

THE object of this paper is to suggest that the need of rest after operations has been greatly exaggerated, with the result that patients are kept in bed much longer than is really necessary. Traditions and long-established habits are generally followed blindly and without question, whereas it is our bounden duty, in the interests of progress, to submit them to criticism, to continue what is good, to cast aside what is useless, irksome, and harmful, and to evolve better and more humane methods. For some ten or more years I have been asking myself the following questions:

Is it necessary or kind to insist on so much rest? Is it not dangerous, as well as irksome to the patient? Is it economical—in the widest sense of that word—to keep patients in bed and in hospital for such a long time? Do not unnecessary restrictions add to the personal fear, as well as to the danger of operations? Is it true that wounds heal faster and better when at complete rest, or that they may give way when patients are allowed up early for gentle exercise?

As a result I have gradually changed, and I hope and believe greatly improved, the after-treatment of my patients. I submit that many of the dangers of operations are due to unnecessary restrictions imposed during this time, and that the public fear of operations is very largely due to the same cause. My patients often tell me that, if they had known beforehand how simple and comfortable the after-treatment could be made, they would not have hesitated so long before undergoing operation. For this reason it is kind and wise to describe and explain the plan of after-treatment before the operation, so that the patient may expect and welcome the method. It cheers him to know that he may move as much as he likes in bed from the first, have the freedom of the room after four days, of the bath after seven days, and may take short walks or drives in the open air after ten days.

It is true that rest in bed is valuable while the nervous system is exhausted and the body is in pain immediately after a severe operation, but when reaction has set in and pain and tenderness have subsided, as they generally do after a few days, it is no longer necessary. Nay, the normal mind and body chafe under undue restrictions and want to return to more natural conditions and habits as soon as possible. Complete rest in bed depresses the spirits and lowers the physiological actions and general vigour of the body. The heart beats less frequently and less forcibly; the breathing becomes slower and shallower; the appetite fails; the digestion flags and the bowels become sluggish. Under these conditions the risk of clotting of the blood in the auricular appendages and in the veins is increased, and it is a matter of experience that thrombosis and pulmonary embolism are far more likely to occur in bedridden patients. The best way to avoid these serious complications is to keep the patient and the blood stirring. Clots large enough to obstruct the pulmonary artery take some time to form, and it is known that such clots rarely cause fatal embolism within the first week of an operation. The catastrophe nearly always takes place between the eighth and seventeenth day. It appears to be easier to avoid the formation of clots than to prevent their shifting, and I therefore keep my patients moving as much as possible from the beginning, getting them to walk a little within four or five days of the operation, unless there is some grave contraindication. As a result I very rarely see thrombosis or pulmonary embolism now.

It is, again, well known that the dangers of hypostatic pneumonia and other pulmonary complications are greatly increased by the incomplete aeration and congestion of the bases of the lungs which prevail in bedridden patients. The muscles, especially those of the legs and abdomen, begin to waste and lose their tone after a few days in bed, and this deterioration progresses so rapidly that standing and walking become more and more difficult. By getting up early and walking a little every day this loss of power is prevented and the need of massage abolished.

Undue adhesions of the viscera to each other and to the parietes, and of the various layers of the abdominal wall to each other, can be very largely prevented by early voluntary movements. For instance, many patients kept too still in the

sitting up and flexed positions, find it difficult and painful to straighten their bodies and hips on getting up, whereas if they are encouraged to move freely and get up early they are spared these troublesome complications, for any adhesions that form are sufficiently stretched while they are still soft and comparatively painless. It is far easier and better to prevent limitation of movements from adhesions than to correct these limitations once developed or confirmed by the prolonged adoption of unnatural positions during healing. Man is punished by his limitations, not by his movements.

Constipation is usual, if not invariable, when patients are kept in bed too long after operation, whereas it can be minimized, if not entirely avoided, by letting the patient get up early, take gentle exercise, and adopt the natural position for defaecation. Constipation, besides being very unpleasant and troublesome to the patient and nurses, brings many evils in its train, such as loss of appetite, excessive straining and the purgative habit, which is difficult to abandon afterwards. It is probable that it also increases the risk of infection of the blood stream and thrombosis. Excessive straining is to be avoided, for it is certainly a severer test on an abdominal or hernial wound than gentle walking exercise.

As regards the healing of wounds, years of observation have convinced me that complete rest is unnecessary and even harmful by interfering with general and local circulation and nutrition. I have no recollection of any delay of healing due to getting up early and taking gentle exercise, nor have I ever seen hernia develop or recur from this cause. Fractures of the ribs always join promptly and well in spite of the inevitable movement of the fragments. Similarly, gentle movements of wounded soft parts do not hinder but help the process of healing. Confinement to bed, or even to a room or indoors, almost inevitably deprives patients of some of the great benefits of fresh air, light, and sunshine, which have a most stimulating effect upon healing of body and mind, as was well shown during the great war.

It is not economical to keep patients so long at rest in hospital. Let us take appendicectomy and the radical cure of hernia as examples. Patients are generally kept in hospital for about three weeks after these operations; whereas, even under present conditions, they can safely leave after ten days, or even earlier. Under ideal conditions—as, for instance, the existence of a simple and economical convalescent home or camp in the country—they could be moved there after four or five days, for these patients need very little nursing or medical attention after that time. In this way two or three times as many patients could derive benefit from the charity, or, as an alternative, the number of hospital beds in London could be greatly diminished. Very soon the long and costly delay in getting into hospital would be abolished.

Much thought, trial, and observation have convinced me that the ideal after-treatment cunningly combines rest with exercise and freedom—at first much rest and little exercise, later less rest and more exercise every day. The sooner the normal habits of life are restored the better. I have learnt much from children and infants, who are difficult to keep still, and yet heal and recover better than adults.

I do not claim that the views I venture to express are original, but (what is far more important) I believe them to be true, and that a reasoned account of them is long overdue. That there is need of it is evident to anyone who cares to look around and think. A few brief examples which have recently come my way may help to show this.

A short time ago I saw a surgeon of ability and repute fix a child in a long Liston splint after the radical operation for hernia—surely an unnecessary punishment. A lady, after an operation for acute appendicitis, with pelvic peritonitis, was, in spite of instructions, kept in the Fowler position, with a pillow under the knees, for a month, with the result that she could not stand or walk in the upright position for three months, and even then required massage for her withered legs. Again, an elderly gentleman, having had his gall bladder removed in New Zealand in April, came to see me in October because he leaned forward and to the right, and could not stand or walk about without pain in his right flank, due to adhesions and retractions of his abdominal muscles. He had been kept at rest, in the sitting-up and flexed position, and had been asked to keep as still as possible in order to ensure healing. Compare this result with that of a patient who, after cholecystectomy and cholecystectomy, went home on the twelfth day and voluntarily walked up three flights of stairs to his bedroom in London. Two days later he motored thirty miles to his cottage in the country, and three weeks later, after a perfect

holiday, returned to his professional work in London in excellent health.

It is not suggested, however, that patients should be hurried back to work, or that all should be treated alike, for many need a longer holiday than others, and after some operations a long convalescence is essential. For instance, some overworked or exhausted patients, even after comparatively small operations, require a long convalescence to restore them to health; but the rest and change from work is all the more effective when it is combined with gentle, interesting, and increasing exercise, with mental diversion. Similarly, after gastro-jejunostomy, especially for an active duodenal ulcer, prolonged convalescence and dieting for from two to three months are necessary to ensure permanent healing of the ulcer and stomach, but only the first few days of this period need be spent in bed. The greater part can be passed over profitably in the open air, taking gradually increasing exercise, just short of fatigue, so that the patient becomes strong and well before he returns to work, about three months after the operation.

THE TREATMENT OF TUBERCULOSIS WITH COLLOID OF CALCIUM.

BY

EDWARD E. PREST, M.A., M.D. CANTAB.,

MEDICAL SUPERINTENDENT OF THE AIRSHIRE SANATORIUM, AND
CONSULTING PHYSICIAN TO THE AIRSHIRE COUNTY
TUBERCULOSIS COMMISSION.

It is generally admitted that the present methods of treating pulmonary and also so-called surgical tuberculosis leave much to be desired. The methods suggested have been numerous, but a great deal of controversy is always in progress as to their respective merits. The dispute over tuberculin is perhaps the most familiar example of divergence of view. I am of opinion that the conflicting views on the value or otherwise of tuberculin arise from the two-edged nature of this substance, which although undoubtedly beneficial in some cases is harmful in many others; the difficulty of differentiating these cases without actual experiment makes many very chary of using the remedy.

With regard to new remedies there is always the difficulty of deciding whether any given improvement or other change is due to our treatment or is the result of the vagaries of the disease. Many new methods of treatment have apparently yielded good results in the hands of those who first used them, but have after a time been abandoned; this makes it appear possible that some of the results were psychic in origin, and it is therefore with some diffidence that I bring a new remedy to the notice of the profession.

In the BRITISH MEDICAL JOURNAL of March 19th, 1921, page 420, I published some remarks on the treatment of tuberculosis by means of calcium. There was considerable variability in the results obtained by the administration of calcium lactate—the particular salt I used—and it occurred to me that this might be due to differences of absorptive capacity in different individuals. I therefore cast about for some other method of administering the drug. I had at that time, for a rheumatic condition, been using with success some colloidal iodine prepared at the Crookes Laboratories. I therefore asked whether I could obtain calcium in the colloidal state, and was informed that at the suggestion of Sir Malcolm Morris—who I may say has taken a great interest in this investigation—they had just prepared some colloidal calcium and sent me a supply to try.

Mr. J. F. Ward, the chief chemist at the Crookes Laboratories, who has rendered me every assistance in this investigation, tells me that the calcium is protected by glutamic acid, which is prepared from gelatine; this is autoclaved to 140° C., which guarantees freedom from living organisms and spores. The strength is 1 in 2,000, representing the actual amount of calcium present, the amount of calcium oleate being approximately seventeen times as much. The colloidal calcium, when examined with the ultra-microscope, is seen to be in active movement. The fluid is homogeneous, has the appearance of milk, and easily passes through a very fine hypodermic needle.

The drug is administered hypodermically. I inject it under the skin of the back of the forearm, as that situation is easily accessible, and the local reaction can more easily be observed. The skin is rendered aseptic, and the injection is made with

a Record hypodermic syringe graduated in tenths of a cubic centimetre. I use a very fine steel needle which renders the injection little painful—a matter of some importance. Veins should be carefully avoided. I have used an initial dose of 0.5 c.cm., the average dose used having been 0.7 c.cm., and I have not given larger doses than 1 c.cm.

The actual dose of calcium is extremely small, and I would warn any who are inclined to use this remedy not to increase the dose without due consideration; those indicated appear to have been quite sufficient. For instance, in a very acute case with very high temperature and night sweats I gave 1 c.cm., and the sweating ceased for ten days, but the temperature remained rather higher, and no benefit apparently followed. I have not yet quite decided as to the correct spacing of the doses; as a rule I have given them every five days to begin with, but I am not sure that a week is not a more satisfactory interval, and in some cases an interval even longer is perhaps better. This point must be decided by the general clinical condition of the patient.

There is generally some local reaction at the site of the injection visible the next day. This is a very variable factor, in some cases it is almost negligible, in a few severe; in one case which was suffering from tuberculous glands with discharging sinuses, the first reactions were very pronounced, and the second caused swelling of the whole of the forearm from the wrist to the elbow; nothing was done in the way of treatment; she continued her work as usual, and the swelling and redness disappeared in three days; as she was feeling so much better and the sinuses had ceased to discharge, she cheerfully went on with the treatment. I have not yet been able to satisfy myself whether there is any connexion between the amount of reaction and the amount of benefit or otherwise which follows, but it is quite possible that this can be worked out with more experience.

Most of the patients make no complaints after the injections, but certain symptoms follow in others. Vomiting occasionally occurs the day after an injection, and in some few cases palpitation has been complained of; in one case there was a complaint of giddiness; this, however, soon passed off, and no treatment was necessary except that it is perhaps advisable to decrease the dose and lengthen the intervals. One beneficial result of the injections is that in many cases the patient sleeps very much better. I generally give the injections in the evening, so that patients will not be taking exercise until the next morning. Where a patient is suffering from fever it is well to be cautious, as it sometimes happens that the injections are followed by a rise of temperature and the symptoms of a mild tuberculin reaction, including increase of sputum. The rise in temperature has never been much in my cases. I have given over 800 injections, many of them to young children of 5 or 6, and I have never experienced any anxiety—a very different experience from that one has when giving tuberculin.

All the 56 cases upon which this account is based, with the exception of one which was a domiciliary case, were living under sanatorium conditions—favourable conditions to improvement; the temperature in all cases was taken in the rectum, and I believe unless this is done it is impossible to gauge properly the effect of treatment. I would urge those who try this remedy not to omit keeping their patients in bed if they are suffering from fever.

I commenced treating cases with colloidal calcium at the beginning of July, 1921; for obvious reasons I have to confine my report to immediate results which could be most easily observed. Of 56 patients treated 24 were males and 32 females. Owing to the less stable metabolism of calcium among females than males, we might expect that administration of calcium would be more beneficial in their case; nevertheless a considerable number of males benefited. It should be remembered that the actual amount of calcium given was extremely small.

Of the 56 cases treated 24 were males and 32 females. Of the 24 males 10 had tubercle bacilli in the sputum, and of these 3 lost them during treatment. Of the females 9 showed tubercle bacilli and 2 lost them.

Among the males, hæmoptysis ceased in 4 cases, the temperature became normal in 1, the sputum dried up in 2 and became much less in 4 others; in 1 case breathlessness was markedly lessened, and in another with limitation of night sweats there occurred marked improvement in acne. One case suffering from Pott's disease showed much less spinal irritability. One case was doing so well that it was impossible to ascribe any of the improvement to the calcium. In 2 cases the general improvement in energy and appetite

was very marked, and in the remaining 7 no change was observed.

Of the females, in 1 case persistent epistaxis ceased; in 3 cases night sweats ceased and the temperature fell to normal; in 2 cases the night sweats ceased but the temperature did not fall; in 1 case night sweats ceased but the temperature rose slightly, but on continuing the treatment the temperature again became normal. In 2 cases the sweating was reduced but did not cease. In 2 the temperature was reduced to normal with improvement. In 1 the sputum was reduced. In 1 breathlessness became much less. In 2 sputum containing tubercle bacilli appeared for the first time. In a spinal case irritability became less; 10 cases improved markedly in feeling of general well-being, and in 5 no change was observed.

The more immediate effects of treatment can be gathered from a perusal of the above, but I may say in passing that some of these cases have improved in a phenomenal manner, the majority being cases of long standing. The case having persistent epistaxis had suffered from it on and off since 1914, and just before the treatment was begun she was having attacks of epistaxis several times a day; after seven injections this completely stopped, and she had had none for six weeks; in addition she is not now short of breath, is feeling very fit and well, and is working hard as a ward maid. She was formerly an inmate of the Ayrshire Sanatorium. It seems difficult in this case to confuse cause and effect. One of the patients in which the haemoptysis ceased, had been having small haemorrhages for weeks; he has now been free for two months and tubercle bacilli have disappeared. One of those in whom the sputum dried up had had it for years; in addition her temperature has fallen to normal and she is able to do her work with comfort. One of those in whom the breathlessness was very much relieved has been under my care almost continuously for eight years; about four years ago I produced a partial pneumothorax in this case, without any improvement, and she then became quiescent under Spengler's I.K. therapy, but she was always troubled with shortness of breath when she gained weight. Since she has had the calcium she has gained over half a stone in weight and is less short of breath.

One of the cases in which the night sweats ceased and the temperature fell was very remarkable: she had been in bed in this sanatorium for seventeen weeks, with a continuous high remittent temperature; she had been ill for a long time, and was what is called a "third stager," with tubercle bacilli in the sputum; she had been treated by rest during all this time, and also with calcium lactate, but although an excellent patient she was no better. She was one of the first cases on which I tried this treatment: at the end of six weeks her temperature was normal, the night sweats ceased almost at once, and by the time she went out tubercle bacilli had disappeared, and she was very much improved.

In two cases something like a reaction occurred, as after the first injections sputum appeared for the first time containing tubercle bacilli. One was a patient who had been under my almost continuous care for six years; she had never had a normal temperature during that period, and was very breathless, largely owing to the extent of the disease reacting adversely on the heart. She has continued the treatment because she feels so much less tired after the injections, but is at present very ill. The other was a girl also with extensive disease, and I was much puzzled why she had no sputum; in this case the treatment was continued and the sputum is much diminished, and she is feeling very well. These two cases may serve as a warning that colloid calcium has in some cases a direct action on the lesion.

Colloid calcium would seem to be beneficial in surgical tuberculosis, for in one of the cases tuberculous glands rapidly diminished and sinuses dried up. In two cases of caries of the spine, in one of which paraplegia had been present for some months but had disappeared before I started the treatment, the remaining spinal irritability, as shown by increased knee-jerks and pronounced ankle clonus, became very much less, the latter being quite unobtainable on some days. In the other the knee-jerks became much less exaggerated and the temperature tended to fall.

The action of the calcium can, perhaps, to some extent be explained by a consideration of its effects. We believe that in a considerable number of cases it stops sweating; sweating lowers the temperature and therefore in those cases in which the sweats cease and the temperature falls there must be some other action at work, which, however, might be

explained similarly; the benefit may be due to the less permeability of the toxins shielding the remainder of the body tissues from poison derived from the lesion; the drug might by this action restore patients saturated with toxin to such a condition that they might ultimately be able to use toxin to form antibodies. I am inclined to think that a certain number of so-called chronic cases which exhibit a normal or subnormal temperature may really only have lost their sensitiveness and are being continuously poisoned by toxin, but are unable to react by a rise of temperature; many of these cases are doubtless thought to be doing well in sanatoriums, but their subsequent history differentiates them from cases in which a normal temperature indicates cure of the disease. Probably such cases will benefit by the administration of calcium. The two patients mentioned who lost their breathlessness may both come under this category, the breathlessness being due to toxæmia.

I think that colloid calcium may have a wider application in medicine than the treatment of tuberculosis; it may prove useful in rickets where there is a deficiency of calcium salts and where there is a great tendency to sweat. It is significant in this connexion that cod-liver oil is very useful in both these diseases. I would suggest that if colloid calcium be tried on quite young children a small dose of 0.1 c.cm. be first given, to be increased until the optimum dose is found. It is probable that adenoids would also be benefited, and the same caution would apply here.

In conclusion, I wish to express my thanks to Sir Malcolm Morris for the interest he has taken and the encouragement he has given me during this investigation, and to Mr. J. F. Ward, chief chemist to the Crookes Laboratories, for preparing the drug and for much valuable information concerning its properties.

POST-OPERATIVE HAEMORRHAGE.

BY

FREELAND FERGUS, M.D., LL.D.,

CONSULTING SURGEON, GLASGOW EYE INFIRMARY.

In connexion with an extremely interesting communication made by Messrs. Pringle and Stewart and Professor Teacher in a recent number of the *Journal of Pathology and Bacteriology*,* the case hereafter recorded may be of some importance, for it seems to be analogous to the cases of post-operative haematemesis which they have described. I have now had a large experience of ophthalmic operations, but as far as I recollect I have never had a similar incident. Fortunately the patient concerned did not succumb to the condition. He made an excellent recovery, and therefore an accurate diagnosis of the source of the haemorrhage is impossible; only inferences can be made.

I performed the operation of cataract extraction one afternoon about 2 o'clock on a gentleman well over 70 years of age, being assisted thereat by my friend Dr. McMillan. The patient had been in a nursing home for a considerable time before the operation, for, at his first admission, inoculation of serum agar tubes with the conjunctival fluid gave a fairly active growth of *Staphylococcus albus*. I therefore had resort to the saline douche, which was applied every few hours for some days till the culture gave only two small colonies. When this condition of comparative sterility had been obtained I determined to operate. There was thus ample opportunity of observing his general condition prior to the operation. To all appearances he enjoyed excellent health; he took a full but plain diet, and in every way had a relish for food and never complained of the slightest pain. For years he had been in the habit of taking a mild aperient as occasion required, and this he continued to do while in the nursing home. The urine was found to be free from albumin and sugar. He was for his years possessed of a most unusual degree of vigour, both mental and physical. The only incident in his previous medical history which seems worthy of record is the fact that when a young man he was considerably troubled with epistaxis.

The operation of extraction gave no trouble; the lens came out quite easily, and an iridectomy was made; although the eye was highly myopic there was no escape of vitreous whatsoever. Altogether the conditions seemed very favourable. I visited the patient the same night about 10 o'clock, and found him as comfortable as could be expected. Following

* An account of this paper was given in the *BRITISH MEDICAL JOURNAL*, December 24th, 1921, p. 1032.

my invariable custom, I gave him liberty to lie in whatever position he found to be most comfortable. He made no complaint, and seemed to be doing quite well. The following morning I was summoned urgently to see him. On my arrival in his room I ascertained that about two in the morning he had suddenly been seized with very acute pain in the neighbourhood of the stomach; this had lasted for some considerable time, and had been followed by severe vomiting. The matters vomited had been retained, and I found on inspection both of the contents of the vessel and of the bed-clothes, which had been stained by some of the vomited matter, that there had been severe haematemesis. The coloration of the vomited matter was dark brown, but in the vessel I found also some fresh blood. I immediately notified myself of the services of a physician, who gave him a prescription, chiefly consisting of bismuth, and gave directions as to the feeding. When I saw him in the morning after the vomiting I found him considerably collapsed, and complaining of great weakness. Evidently he had suffered very severely from pain. Fortunately there was no recurrence of the haemorrhage, and ultimately, as already intimated, he made an excellent recovery. In view of the communication already referred to, the possibility of the case having been one of oesophageal post-operative digestion cannot be overlooked. Such severe symptoms after catarrh extraction was an entirely new occurrence in my experience.

ANTIMONY IN LEPROSY.

BY

G. H. WILDISH, M.B.

M.O. AMATIKULU LEPROSIT INSTITUTION, ZULULAND.

few of the reported benefit derived from the antimony treatment of some Indian lepers at Durban in 1920, Dr. F. G. Ston asked me to give antimony a trial on a more extensive scale amongst natives at the Amatikulu Leprosy Institution in Zululand. No special treatment for the disease had been used there, reliance being placed on fresh air, good, careful dressing of ulcers, cod-liver oil, and to a lesser extent almond-oil by the mouth.

I decided to test oscol stibium in the treatment of twenty of the worst cases, mostly cripples who were being housed in central hospital while awaiting death. The majority of these cases received doses of the drug intramuscularly, 2.5 c.cm., 3 c.cm. and 6 c.cm. on consecutive days. Three weeks later 4.5 c.cm. and 6 c.cm. were given on consecutive days. This series of two doses was repeated during the next two months, making a total of about 40 c.cm. injected. Beneficial effects were seen in the relief of paralysis, drying of ulcers, and in the general condition of all the patients treated except one, who has shown no change at all so far. Similar successful results were obtained from the use of Stokes's colloidal antimony, which proved more toxic and less effective; equally good results were obtained in a few cases treated with tartar emetic intravenously.

Over 1,000 injections have been given at the Amatikulu Institution during the last six months; there has been no serious local inflammation and no abscesses. In each case the needles and syringes were sterilized before use by means of eucalypti biniodide in methylated spirit followed by pure methylated spirit, and the site of the injection was sterilized with mercuric biniodide solution.

Although antagonistic to the treatment when first adopted, leprosy patients have developed a great belief in its efficacy, and in most instances have themselves requested that it should be continued. In the case of Zululand this request is very significant—they do not like medicine injected.

At the present time (July) 98 female natives and 131 males are being treated with various preparations of antimony; 4 of these have recently been treated with ethyl esters after two series of injections with antimony, and their progress points to the efficiency of the combination.

Although still in its early stages, the results at the end of six months have been very encouraging, and suggest antimony in considerable doses for short periods, with intervals of three weeks between each series, as a great help in treating leprosy and possibly as a cure in some cases. It is useful in combination with ethyl esters and sodium cacodylate.

The following cases illustrate the use of the drug, especially in very severe untreated cases.

CASE I.

Native male; on January 20th, 1920, he was not expected to live much longer. He was partially paralysed in both legs and had lost all the toes on one foot. There was marked paralysis of the face and eyelids, so that he could close his mouth only by means of his hand. Dry keratitis had supervened as a result of the facial paralysis, but was not advanced. He received 2.5 c.cm., 3 c.cm., and 6 c.cm. oscol stibium on three consecutive days. Three weeks later the paralysis of the legs had much improved, he had taken food better, put on weight, and felt more comfortable in every way. Since then he has received four more series of injections, 3.5 c.cm. and 6 c.cm. being given intramuscularly on consecutive days. To-day (July 20th) he can walk regularly to the dispensary, a distance of 200 yards or more, and is to be seen walking about the place continually. He can close his mouth without help and chew his food. His eye condition is much improved, but he cannot yet quite close the lids. The treatment is being continued.

CASE II.

This is also a case of meleno-anæsthetic leprosy, showing partial paralysis of the legs and face with conjunctivitis. He received the same treatment and no other during the last six months. The eye condition has entirely cleared up and the lids have returned to normal. Although there is still some weakness of the legs, he is now able to walk without difficulty and has considerably improved in general health. Both these cases showed lepra bacilli in scrapings taken from the nasal septum and were passed as leprosy by several boards. Without treatment both would certainly have died before now.

CASE III.

This native female was very emaciated and feeble. She had also been placed in the hospital to die. There was no paralysis. The macular areas were raised over nearly the whole of the back about one-eighth inch above the normal skin; they were rough and one of them covered a square foot of the surface of the back. She received the treatment outlined above. After the first series of injections the most remarkable results became evident, the whole area desquamating and leaving patches of healthy skin with small ulcerated areas. A somewhat similar result was obtained by Dr. Cawston in the treatment of Nankakha, as reported in the BRITISH MEDICAL JOURNAL on December 4th, 1920, pp. 855 and 856. The skin of this Amatikulu patient was anæsthetic throughout, but after the injections the affected areas began to itch and caused her to scratch herself. On July 19th the skin was almost normal, a trifle lined, with a slight mottling of colour only. She is now walking about easily, is eating well, and feels well.

CASE IV.

This native woman was also in a dying condition; she was a case of meleno-anæsthetic leprosy with enormous discharging ulcers extending from the knees to the feet. She was very thin and weak. She received the same doses. The ulcers cleared up very rapidly at first, and, although there are still a few small sores, the extensive ulceration has healed up much more rapidly than a burn over such a large area would have been expected to do. To-day (July 19th) she feels well and walks about easily all over the place. Throughout the injections the ulcers have been treated locally, as they were treated before the commencement of the antimony course.

CASE V.

On January 20th this native boy of 11 years was considered to be dying. He had enormous tubercles all over the face which might be described as confluent. On one of the feet there was a perforating ulcer 2 inches in diameter. He was given 2.5 c.cm. of colloidal antimony intramuscularly. This dose gave rise to a very severe reaction and for a week his condition was very grave. At the end of the week, however, he felt so much better that he requested me to continue the injections and 3.5 c.cm. were injected without ill effect; 6 c.cm. were given on the following day. All the tubercles shrunk immediately so that their summits looked feathery as a result of acute desquamation. This desquamation has occurred after the other series of injections. On July 19th the tubercles, though present, were much smaller and retracted. The boy is taking his food well and feels well. The ulcer on the foot healed rapidly and has not caused any further trouble.

CASE VI.

This native man showed macular areas all over his face and body, these leprosy areas were depigmented and anæsthetic. He improved very rapidly after the first series of injections in February. The spots began to regain their pigment and the sensation of pain returned. The sweat glands returned to normal in the leprosy areas, so that the skin regained its normal appearance and became shiny. To-day there is only a slight mottling of the skin to indicate previous disease.

At a later date it is hoped to give a more extensive report of the effect of antimony on a large series of cases, but at the end of six months' treatment one can say without fear of contradiction that antimony has a very decided value in the treatment of leprosy patients, more particularly those who are exhibiting severe manifestations of the disease. Dr. Andrew Balfour of the Wellesboro Barcan saw these cases when visiting Natal, and they have been inspected by a considerable number of medical men from various parts of South Africa who are interested in the progress of the treatment.

THE ANTE-NATAL TREATMENT OF CONGENITAL SYPHILIS WITH SALVARSAN AND MERCURY.

JOHN ADAMS, F.R.C.S.

In his article in the JOURNAL of November 26th (in the course of which he refers appreciatively to my cases at the Thavies Inn Clinic) Dr. Leonard Findlay states, "That the curative treatment of congenital syphilis, if not a failure, is at least a great disappointment, no one who has had much experience will deny." As this statement is opposed to my experience, I should wish to point out some difficulties Dr. Findlay has had to contend with in treating his cases, and to express the opinion that, had other methods been used, very different results would probably have ensued.

I will begin with Dr. Findlay's last paragraph, in which he says that all his cases were out-patients. In such circumstances the treatment of congenital syphilis would certainly be unsatisfactory and disappointing, for a large number of syphilitic babies would have died before it was possible for them to be treated as out-patients.

I would strongly urge that the best time to treat all cases of syphilis, whether ante-natal, post-natal, or acquired, is the earliest possible moment available, and this applies especially to newly born babies. I have seen several cases which, had treatment been delayed for a few days, would certainly have died. Babies have been treated at the Thavies Inn Clinic within a few hours of birth, and one of the earliest under an hour, with good results and perfect safety.

Pain is mentioned as a drawback to the treatment of post-natal syphilis, but if galy! in glucose is used intramuscularly in appropriate doses according to the age and weight of the child, no discomfort follows its use, and all the advantages of salvarsan are obtained.

Dr. Findlay's reference to "limits of curative treatment" is somewhat confusing, for he states: "In any case the curative treatment has the great shortcoming that it only influences the disease in children born alive, and neglects altogether the ravages during intrauterine life." If this paragraph refers to post-natal syphilis, one knows how difficult such cases are to deal with if allowed to go untreated for a year or more.

Under the heading of technique it is stated: "Administration of salvarsan in infants and children by the intravenous method considerably limits its use." Intravenous injection for babies and young children appears quite unnecessary, and in many cases would be impossible; injection into the superior longitudinal sinus is open to still greater objection, as at all times there must be a certain amount of danger; but intramuscular injection of galy! in glucose in the gluteal region is perfectly safe, painless, and effective, and should be adhered to in all cases of newly born babies and young children.

In his remarks on the time of election of treatment Dr. Findlay asks the question, "Should the treatment be carried out as soon as the diagnosis is made, or should it be delayed until the woman is pregnant?" My practice is to treat the patient at the very earliest opportunity and continue for a prolonged period—two years if possible.

The method of breast feeding as advocated by Dr. Findlay has brought about the best results in the cases under my care, but it is frequently found necessary to supplement it by some form of artificial food, and all patients, whether babies or adults, should be given mercury as well as salvarsan.

The accompanying table shows the result of treatment of

Result of Treatment of Women during Pregnancy and of the newly born Children.

Years (September 1st to August 31st).	Mothers Admitted with Syphilis.	Babies Born Alive.		Babies Dying of Syphilis.	Fœtus Stillborn from Syphilis.
		Wassermann Reaction:			
		Positive.	Negative.		
1917-1918 ...	23	17	6	Three at the ages of 3, 14, 35 days respectively. One, 2 months.	5
1918-1919 ..	30	8	21	None	1
1919-1920 ...	37	1	36	None	0
1920-1921 ..	23	5	16	None	2

Neither of the mothers had treatment before admission and both were confined of macerated babies soon after.

Treatment of Babies.

Treatment	Wassermann test of		
	Mother	Placenta	Baby
No treatment
	Intramuscular Galy! in glucose!	Intramuscular lig.	Oral lig.
1st day ...	1.25 cg.
8th ..	1.5 cg.	1/8 gr.	1/2 gr. daily Hyd. & creta
22nd ..	2 cg.	1/4 gr.	...
36th ..	2.5 cg.	1/1 gr.	...
Wassermann test.			
50th ..	2.5 cg.	1/3 gr.	...
64th ..	3 cg.	1/1 gr.	...
78th ..	3 cg.	1/3 gr.	...
Wassermann test: Nearly all babies become negative before or at this period.			
120th day...	3.5 cg.	1/3 gr.	Intermediate
134th ..	3.5 cg.	1/3 gr.	treatment.
148th ..	3.5 cg.	1/3 gr.	...
176th ..	Wassermann test.		

At the ninth and twelfth months courses of three injections of 4 to 5 cg. galy! and 1/2 grain mercury should be given, and gr. 1 hyd. & creta daily for a month. Further treatment is governed by the progress of the case. Should the Wassermann test become positive at any future date intensive treatment should be begun immediately. These doses are calculated for babies of normal weight for their age.

women during pregnancy and of the newly born children at the Thavies Inn Venereal Centre for Pregnant Women during the four years it has been open. I append also a tabular outline showing the method of treating babies adopted at the clinic.

Do not usually require the full course of treatment.
To be obtained in 2.5 and 5 cg. ampoules from the Anglo-French Drug Co., Ltd., 238a, Gray's Inn Road, London, W.C.1.
Mercurial cream for adults, 40 per cent.; for babies, 20 per cent. Can be obtained from Squire, 411, Oxford Street, W. A special syringe, which can be obtained from Montague, 69, New Bond Street, W., marked with fifteen divisions, each of which is one-fortieth of an cubic centimetre, is recommended. With 40 per cent. mercurial cream each division contains 1 cg. or gr. 1/5 of mercury.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF MENINGITIS SIMULATING TETANUS.

H. S., aged 47, came to the Casualty Department of the Radcliffe Infirmary, Oxford, on November 4th complaining of pain in the neck and abdomen and stiffness of the lower jaw. Six days previously he had fallen off his bicycle, cutting the inner aspect of the left thumb on a bucket he was carrying. The wound was carefully cleaned at the time and dressed on the succeeding days.

On admission there was some slight rigidity of the neck muscles and definite stiffness of the lower jaw, which he was unable to open more than about half an inch. A provisional diagnosis of tetanus was made and he was admitted, although in view of the fact that since the day of the injury he had repeatedly expressed his fear of contracting tetanus, it was thought the symptoms might eventually prove to be functional. On admission antitetanus serum was given as follows: Intrathecally, 7,000 units; intravenously, 10,000, and subcutaneously, 10,000. The cerebro-spinal fluid removed was clear and not under increased pressure. The following day his condition was much the same; there was trismus and rigidity of the neck, but no opisthotonos, risus sardonicus or general muscular spasm, squint or photophobia were noted, but he complained of headache. The knee-jerks were brisk and the plantar reflex flexor; the bowels were constipated. There was retention of urine; on passing a catheter a mucral discharge was noted.

Later in the day he was seized with a sudden spasm of the glottis and became cyanosed and pulseless, but was revived by artificial respiration, etc. He was now unable to swallow either solids or liquids, as any attempt to feed by mouth tended to bring on another spasm of the glottis. The case was now diagnosed as one of cephalic tetanus.

In the course of the next day, forty-eight hours from the onset of symptoms, he had several similar spasms, and died during one of them, in spite of the hurried performance of tracheotomy. The temperature was subnormal throughout; the pulse varied between 60 and 80. There was never any general muscular rigidity, but the spasm of the jaw never relaxed.

The patient was seen by several medical men familiar with tetanus, and the general consensus of opinion was that the clinical picture, whilst not quite that of ordinary tetanus, most nearly resembled that of so-called cephalic tetanus.

At the necropsy the lungs and the right side of the heart were found deeply engorged; there was no tracheal or laryngeal obstruction. The convex surfaces of both cerebral hemispheres were

covered with a yellow purulent exudate. The base of the brain was normal in appearance. In a direct smear from its surface no organisms were seen. A culture unfortunately was not made.

Although direct evidence is lacking, it seems possible, in view of the chronic gleet, that the case may have been one of gonococcal meningitis.

I am indebted to Dr. Collier, under whose care in hospital the case was, for permission to publish these notes.

L. S. FRY, M.R.C.S., L.R.C.P. (Lond.),
Late House-Physician, Radcliffe Infirmary, Oxford.

ŒSOPHAGEAL POUCH.

S. L., aged 5, was admitted to the Glan Ely Tuberculosis Hospital of the Welsh National Memorial Association on October 22nd, 1921, as a suspected case of tuberculous peritonitis and cervical adenitis. The history was that the child had been quite well until eighteen months earlier, when she swallowed caustic soda accidentally. Since then she had been ailing and getting progressively thinner, vomiting more or less regularly every few days. The child was wasted and emaciated and weighed only 1 st. 10 lb. 10 oz.; although showing possibly some of the stigmata of tubercle there was no definite evidence of any active disease. The abdomen on physical examination did not show any marked pathological condition.

The child was put on a light diet, but it was found that she was able to take very little; she vomited very frequently and probably brought back the greater part of whatever was swallowed. The vomited matter was alkaline or faintly acid; a fluid diet was tried with no better result. The bowels acted fairly regularly; the motions were loose and pale. The vomiting took place without effort and independent of the time of taking food; after some days of observation the possibility of an Œsophageal pouch was suggested by Dr. Clark, the senior assistant medical officer. A fortnight after admission a hissing meal was given and the chest screened, when a dark image, in shape a somewhat oval pouch, was seen. An x-ray plate showed a distinct pouch of the Œsophagus at the level of the third to the seventh dorsal vertebrae.

As the child was too weak and emaciated to stand any severe or prolonged operation a gastrostomy was suggested as a means of getting her into suitable condition for possible removal of the pouch. The parents, however, refused operative treatment and took her home.

ALEX. BROWNLEE,
Medical Superintendent.

LABOUR COMPLICATED BY MALIGNANT GROWTH.

At 3.30 a.m. on July 22nd, 1920, I was asked by my partner to assist him at a midwifery case. Neither of us had been engaged for the confinement, but a certified midwife was in attendance and had sent for help in the approved form. The woman was 38 years of age, a multipara, and this was her fifth confinement. She was very pale and cachectic, with oedema of the lower extremities and vulva, her pulse small and rapid, the rate 150 per minute, and her respiration sighing.

She had had an extensive hæmorrhoid, and the vagina was filled with a huge cauliflower growth, which bled freely when touched; the foetus was indescribable. After the most gentle manipulation, I found that the greater part of the growth arose from the anterior lip of the cervix. She was anaesthetized with chloroform, and upon passing my whole hand into the vagina I found that the head was presenting but not yet engaged in the pelvic outlet. I also made out that the head was fairly movable. I attempted to pass the lower blade of Barnes's long forceps, but on account of the free hæmorrhage I had to desist. The patient was now in extremis. Foetal movements had not been felt by the mother for the last forty-eight hours; the foetal heart could not be heard; the child was evidently dead. I therefore performed bipolar version and was able to grasp the left foot; the child was easily delivered, but for a little delay caused by the head. The placenta was expressed and appeared healthy; the uterus contracted well. I gave the patient a half-grain morphine suppository. Convalescence from the labour was rapid, but the malignant growth increased, and in the course of a month presented at the vulva. She was then admitted into a neighbouring infirmary and transferred to a Liverpool hospital, where an exploratory laparotomy was performed; the growth was inoperable. She died from

Reports of Societies.

SEPTIC INFECTIONS OF THE BLADDER AND KIDNEY.

At meetings of the Royal Medico-Chirurgical Society of Glasgow, held on December 2nd and 16th, 1921, a general discussion took place on "The diagnosis and treatment of septic (non-venereal) infections of the bladder and kidney."

The speaker, Dr. JOSHUA FERGUSON, confined his remarks to the infectious associated with the *Bacillus coli communis*. This organism, normally harmless and useful, acquired, after leaving its ordinary nidus, a noxious and often dangerous character. In this respect, he suggested that just as the passage of a culture through various special media or certain susceptible hosts exalted its virulence, so the result of implantation upon new tissues might develop the morbid properties of the *B. coli*. The detection merely of coliform bacilli in the urine did not in itself prove the existence of a morbid infection. Often a bacilluria might indicate no more than the elimination of micro-organisms from the body. The lesions of the urinary tract dependent upon infection by *coli* organisms were cystitis, pyelitis, pyelonephritis, and pyonephrosis, or two or more of these may exist in combination or in sequence. The age and sex incidence was of considerable importance in diagnosis, and they occurred with almost equal frequency among the comfortable and among the less favoured classes, suggesting that the well-to-do were relatively more susceptible. Dr. Ferguson described 6 cases of cystitis and pyelitis, more particularly with regard to etiology and treatment, and concluded by emphasizing certain considerations relating to the treatment. In infants especially, but also in others, the early recognition of premonitory symptoms was important, as was, from the point of view of prophylaxis, the development of sound and cleanly functional habits. Diet, modified so as to ensure free internal lavage of the urinary channel, was all-important. Alkalinization of the urine should be obtained at the earliest possible opportunity; where this failed urinary antiseptics of the formaldehyde type (the best seemed to be hexamethylene-tetramine salicylate) were often successful. Regular free action of the intestine was an indispensable part of treatment, and in the infections under consideration the regular use of suitable doses of magnesium sulphate and sodium sulphate had usually a specially beneficent effect. Vaccine therapy in Dr. Ferguson's hands had produced inconstant results.

Dr. LEONARD FINDLAY dealt first with the varied symptomatology, which was especially so in infancy. The clinical picture was, as a rule, that of anything but an infection of the urinary tract, and very many diseases were simulated. Rarely, if ever, was the condition in infancy admitted to hospital with the correct diagnosis. In part this was due to the fact that routine examination of the urine was not carried out in infants. Besides thorough chemical examination of the urine, a microscopic and bacteriological investigation also was essential. An occasional pus cell seemed to be a normal finding, and in febrile conditions shreds of mucus and leucocytes were frequently present. Culture of the sediment of almost any specimen, taken with all due precautions, showed an occasional colony of *B. coli communis* or some other organism. In pyuria pus was present, in most cases, in sufficient abundance to be recognizable without centrifugalization. In a few cases the pus appeared in the urine only sometime after the onset of illness. In bacilluria or bacteriuria, again, the organisms could readily be seen in a fresh drop without centrifugalization, and in films were abundant and cultivated readily (without centrifugalization). Dr. Findlay insisted on the need for obtaining over several months a pus-free and organism-free urine, as far as the fresh drop was concerned, before claiming a cure. One much discussed point was the mode of entrance of the infecting organism. Much experimental work had been done, and the conclusion reached that the passage of the infecting agent up the urethra, if the urinary tract was healthy, was improbable, but this was not so in the presence of abnormality, such as congenital hydronephrosis. Free drainage was necessary to secure the excretion of organisms such as *B. coli*, which passes through the kidney, but where anything interfered with the emptying of the urinary system the organisms multiplied and produced

that the disease commenced as a pyelitis, this was not necessarily so, although it seemed to be so in tuberculosis of the urinary system. Clinical histories and cystoscopic findings were against this contention. Clinically two distinct and different pictures were seen. In infants the disease usually began with great suddenness, with fever and severe toxic symptoms. It was one of the rare conditions in infancy in which rigors occurred. The urine contained pus and organisms, and occasionally small amounts of blood. In older patients there was frequency and pain on micturition and passage of blood at the end of the act, or it might be of a highly blood stained urine. There was no fever. In Dr. Findlay's opinion the latter type was a primary cystitis unaccompanied by pyelitis, and the former a primary pyelitis. The mortality was high in the former and very low in the latter. Observations made by himself and Dr. Repton, using the cystoscope and metal catheter, substantiated the truth of the teaching that primary cystitis did occur.

In conclusion Dr. Findlay said that his sympathies were with the haematogenous school. Various factors influenced the effects of the excreted organisms on the urinary tract and precipitated the inflammation. The disease occurred most frequently in infancy and young childhood, and this might be associated with the frequency of intestinal catarrhs at these times. Such increased susceptibility was seen in the cases of meningococcus, gonococcus, and tubercle bacillus in their effects on the meninges, infant conjunctiva, and lymphatic system respectively in infants.

Professor Carl Browning said it was important to note that cases might be divided into two distinct groups: those with obvious mechanical obstruction where removal of the blockage was mainly responsible for cure, and those where there was no mechanical abnormality and operative measures did not possess the same radical importance. The condition might apparently be primary or it might be a complication in other diseases. In diagnosis the presence of organisms in considerable number in recently passed urine, gross contamination being excluded, could only mean infection in the urinary tract. It must be remembered that it was not possible to determine which portions of the urinary tract were involved by a microscopical examination of the epithelial cells in the urinary sediment. Regarding routes of infection, it appeared improbable that the renal pelvis frequently became infected from the bladder unless there was obstruction. Passage of organisms from the blood stream to the renal pelvis occurred freely, and this probably represented an important route of infection in pyelitis. Infection by the lymphatic route had also to be considered. The bacteria found were most frequently bacilli of the coli group, but staphylococci or streptococci might also be present. In cases of chronic pyelitis, microscopic examination had shown that the bacteria did not merely inhabit the surface, but were lodged in the depths of the tissues and were thus protected from any therapeutic agents which did not possess considerable penetrating power. In considering treatment, Professor Browning referred to surgical measures in chosen cases and the alkalinization of the urine, as recommended by Dr. John Thomson. He also spoke of treatment by vaccines, and while admitting that results were inconstant, thought that they deserved a trial. In regard to the use of urinary antiseptics he referred to hexamine, the flavines, and the recently introduced organic mercury compounds such as mercurochrome.

Sir KENNEDY DALZIEL, in opening the discussion on the second evening, referred to the part played by the surgeon in septic infection of the bladder and kidney. Cystitis was rarely a primary disease, and was due, as all inflammations were, to the access to the bladder wall of micro-organisms. As a rule the symptoms were frequency of micturition, pain and strangury, with, later, alterations in the excretions. In the absence of instrumentation or other traumatism, these symptoms would usually be found to have their origin in pyelitis rather than cystitis. Cases to the contrary did occur, but in practice the bulk of cases had their origin either in the kidney or in the prostatic urethra. All were familiar with cystitis caused by catheterization, even with carefully sterilized instruments, infection being carried from external parts, or even the terminal part of the urethra. It might also be caused by injury with a foreign body and other factors which injured the mucous membrane of the bladder. The condition of the urine itself might play an important part in the causation of cystitis. Retention of urine in stricture and prostatic disease and the presence of blood serum in the urine

encouraged growth of organisms. In the absence of instrumentation, germs found entrance to the blood stream through septic conditions of the teeth, tonsils, and various cavities. Most were destroyed by the blood cells, but when devitalizing conditions arose the organisms were not so destroyed but were thrown out by the kidneys. For that reason surgical operations attended by shock and exhaustion were sometimes followed by urinary infection, without the passage of a catheter. Surgical wounds of the bladder might cause cystitis, and the greatest care and precautions were necessary to avoid the introduction of organisms during and after operation. The after-treatment of prostatic cases was drainage and lavage, and frequent dressing was of the greatest importance. Inflammation of the prostate caused cystitis by direct extension to the bladder and might also cause profuse urethral discharge. The micro-organisms causing cystitis might be any of the pyogenic organisms, but, apart from instrumental infection, it appeared that the commonest infection was that of *B. coli communis*. Additional symptoms in cystitis were pain in the perineum, especially if the prostate was involved, and, in acute cases tenderness above the pubis. In more marked cases blood cells, epithelium, and leucocytes were found in the urine. The urine was acid unless ammoniacal decomposition had set in. The symptoms of pyelitis and prostatitis were very similar, but in the former the tenderness was found in the kidney region, along the ureter, near but below McBurney's point and above Poupart's ligament; while in prostatitis the pain was more marked in the perineum, and was referred along the urethra. Cystitis varied in degree from the merely congestive or catarrhal to the haemorrhagic, the ulcerative and gangrenous, and so also the constitutional symptoms varied. The condition of the urine varied also with the severity of the attack. For the most part the temperature was but little raised in cystitis, while the opposite prevailed in prostatitis and pyelitis, and in these the constitutional disturbance was greater.

For treatment, the first indication was the removal of all predisposing causes—stone, tumour, etc.—and also all causes of obstruction to the outflow of urine must be removed. Citrate of potash and diluents should be used in the milder cases till the urine was alkaline; thereafter the exhibition of a urinary antiseptic, such as urotropine or hexamine, in conjunction with an acid tonic. In more severe cases lavage with saline or boric solution was helpful, and in ulcerative and sloughing conditions suprapubic drainage must be had recourse to. His experience of vaccines had not been altogether favourable.

In inflammation of the kidney the infection almost always took place through the blood stream, and the stricture of the kidney assisted this when organisms were in excess or resistance lowered. True bacilluria might exist for a considerable time without inflammation of the bladder or kidney, causing few symptoms, and those of a vague kind only. Blood might be present in pyelitis, even forming clots. Bladder pain might be very intense and the pain referred along the urethra. The urine was acid and *B. coli* was present; if copious an opalescent appearance was given. There might be tenderness over one or both kidneys. Fever and frequency of micturition might be marked; the former was a constant and important symptom. Acute cases might simulate an "acute abdomen." For treatment, alkalis, plenty of fluid, warmth, rest in bed, freedom from worry, and nourishing light diet, were recommended. The use of collargol in lavage through a urethral catheter, and the free incision of the kidney in acute cases were also mentioned.

Dr. JOHN THOMSON (Edinburgh) confined his remarks to the diagnosis and treatment of acute uncomplicated infection by *B. coli* of the higher parts of the urinary tract as it occurred in children of 2 years old and under. It seemed certain that the colon bacillus causing the infection came from the patient's own bowel. For many reasons it was obvious that the mucous membrane of a normally healthy genito-urinary tract was not readily infected by the *B. coli*. There was reason to believe that in health colon bacilli passed out of the body by way of the urine without doing any harm during their rapid downward passage; for an infection of the tissues of the tract to occur, either (1) the resistance of the tissues had been lowered, or (2) there had been retardation of the flow of urine downward so that the bacilli had been abnormally long in contact with the mucous membrane, or (3) for some reason the organisms possessed increased virulence. In clinical work there was often a history of such weakening diseases as influenza, infantile scurvy, etc., or a local lesion such as prolapse, threadworms, or anal fissure. The most evident

cause of obstruction to flow occurred in cases of congenital hydronephrosis; but it was possible that temporary blocking might occur, which was difficult to demonstrate. A history of severe diarrhoea was very common indeed.

The organisms found entrance into the urinary tract in three ways: (1) By the blood stream, which they had entered through some wound or abrasion of the skin or mucous membrane. (2) Directly through the tissues, especially into the right kidney from an inflammatory lesion of the bowel which lay in close contact with it. The attack often set in during an attack of severe diarrhoea. (3) By an ascending infection passing up the urethra from without, probably only in female cases. The infection might be confined altogether or mainly to one portion of the tract, or it might spread. In most cases it was impossible to obtain light on the distribution of the lesion from any examination of the urine, but information might be obtained by a study of the nature and course of the symptoms. Where the disease was confined to the bladder this might be recognized by the presence of pus and colon bacilli without toxic symptoms, but commonly with very frequent micturition, with or without incontinence. There might be an offensive smell and sometimes haematuria. When the ureter, pelvis, or kidney became infected, acute general symptoms immediately arose with high fever, prostration, nervous irritability, and sometimes delirium. In young infants squinting was common. Where general symptoms were severe from the first there were also signs of acute intestinal disturbance. In girls, also, in about half the cases, the rise of temperature was accompanied by one or more rigors—a rare symptom in infancy. Sometimes there was faintness or even unconsciousness. During the acute stage the respiration was generally accelerated, as compared with the pulse, although the lungs were not affected. Local symptoms, if present, were generally slight, although sometimes distinct enlargement, with tenderness of one or both kidneys, could be made out. A fresh specimen of urine was generally acid and might show albumin. There were usually visible colon bacilli and six to eight pus cells in each high-power field of a drop taken from the middle (and not the sediment) of the specimen. These urinary characteristics, taken along with a characteristic high remittent type of fever which ceased on alkalinization of the urine, constituted the essential elements of a diagnosis of *B. coli* affection of the renal pelvis.

Implication of the kidneys was suggested when the child was much collapsed, and when there was a considerable amount of albumin or when many casts were present. The temperature might be high and irregular or it might be normal or subnormal towards the end. Failure of alkalinization to relieve the fever within forty-eight hours was usually a sign that the kidneys were badly affected. The age and sex incidence was mentioned with regard to frequency and severity of attack. For treatment, plentiful use of fluids by mouth or otherwise was necessary, and one of the following measures: (1) The use of serums or vaccines, (2) administration of antiseptics, and (3) alkalinization of the urine. The first two methods had proved disappointing in Dr. Thomson's hands, and the third method was that usually adopted by him. Potassium citrate, simply because it was the least unpalatable, was the alkaline drug he most frequently used. If diarrhoea was caused, sodium bicarbonate might be substituted. The effect of the alkaline treatment could be well seen on the temperature charts, and the other symptoms always improved when the temperature fell. Doses that were too small exerted no influence on the course of the disease. If the disease had spread to the kidneys to any serious extent this treatment had little if any effect. When there was a mixed infection harm might be done.

Dr. JOHN COWAN remarked that although infection of the urinary passages with *B. coli* was considered to be due to a blood infection, no allusion had been made to blood culture. Blood infection might occur in cases of intestinal infection; it was the rule in enteric fever, and it was common in dysentery. If the assumption was correct, and blood infection preceded infection of the urinary passages, one would expect to meet cases where the general symptoms predominated, and local symptoms were absent or minimal. Such cases had already been referred to in children, but they occurred also in adults. He described two cases in which general symptoms of cerebral type obtained associated with a gross infection of the urine. The urinary symptoms were minimal or absent, and in both improvement in the general symptoms was the result of treatment by alkalis, and coincided with improvement in the urinary symptoms. There was no particular

difficulty in recognizing the condition if search was made for it.

Dr. MARION GILCHRIST referred to the methods of treatment she found most efficacious. These included free purgation, sufficient doses of a paraffin emulsion with salol, which coated the bowel and prevented absorption of poison, antiseptics according to the nature of the case, free flushing of the urinary system, and urinary sedatives. Dr. Gilchrist suggested that there was a wide field for investigation in the study of the part which the endocrine glands played in the defences of the kidneys and bladder.

Mr. J. MILL RENTON differentiated between chronic cases depending on obstruction in the urinary tract and those without obstruction. The former usually cleared up with removal of the obstruction. In the non-obstructive cases the symptoms, mainly pain and frequency, were usually referred to the bladder. Before classing these cases as cystitis a comprehensive examination should be made of the whole urinary tract. Infection of one or both kidneys, or infection of the prostate, might keep up a cystitis. Cystoscopic examination of the bladder should be made in all such cases. By urethral catheterization a specimen of urine should be obtained and examined. Abscess of a kidney was thus detected, and suitable treatment would rapidly clear up the infection. Sometimes a *B. coli* infection masked a tuberculous kidney. The treatment of chronic pyelitis causing cystitis was still far from satisfactory. Bladder lavage and vaccines were unsatisfactory. Lavage or instillation of the renal pelvis got at the seat of the disease more directly than other treatment, but opinions regarding the results were conflicting.

Mr. ARCHIBALD YOUNG (whose remarks were communicated by Mr. SCOTLER BUCHANAN) pointed out that the subject of discussion was not limited to infections with *B. coli*. This failure to recognize the other types of infection might account for the different opinions as to diagnosis and routes of infection and treatment. He believed that a very large proportion of cases were brought about by ascending infection. The late Dr. Lindsay Steven proved beyond dispute that septic infection might spread upward by the lymphatics and give rise to septic lesions in the kidneys. This method of spread might explain many of the supposed blood infections. Admitting that many infections of kidney tissue, etc., were blood infections, the greater number were probably due to ascending infection. A very large proportion of simple *B. coli* infections appearing in later life, and more especially in the female sex, seemed to be recurrences of definite attacks dating back to infancy, or the transformation into active disease processes of simple bacillurias present, it might be, all through life and producing little or no symptom. As to diagnosis, Mr. Young agreed that careful and repeated examination of the urine was necessary, but the clinician's view should not be overshadowed by the pathologist's. There must be, however, unceasing care in observation of the case from every point of view. Treatment must depend obviously on diagnosis and on the route of infection. Vaccine therapy was disappointing, but the alkalinization of the urine had proved an effective measure in his hands associated with free flushing of the renal filter. He believed fully in large doses of urinary antiseptics such as hexamine and salol. His success in using the former was due to the fact that he used it in large doses combined with an alkali, and never with acid sodium phosphate. He rarely employed washing out the bladder in cystitis. Similarly he did not consider catheterizing the ureters was good practice.

POST-OPERATIVE EMBOLISM AND INFARCTION.

A discussion took place in the Section of Surgery of the Royal Society of Medicine on January 4th, on "Post-operative embolism and infarction." The chair was taken by the President, Mr. RAYMOND JOHNSON.

Mr. J. P. LOCKHART-McKENNERY, in introducing the subject, said that with the diminution almost to vanishing point of sepsis and shock, post-operative embolism was probably the worst tragedy of surgical practice at the present time. In one hospital alone there had been 18 deaths in a recent year from this cause. Moreover, the fatal cases appeared to be increasing; the incidence in some hospitals had doubled as compared with a corresponding pre-war period. Cases of embolism might be divided into three categories: (1) those in which death occurred instantaneously; (2) those in which death occurred within a few minutes or hours following an acute and sudden crisis; (3) those in which the patients

veloped signs of consolidation in part of the lung followed a similar crisis, and recovered. With regard to the first of these cases, he believed such sudden deaths could only be accounted for by an embolism in the medulla of the brain; possibly a thrombus formed in one of the pulmonary veins, and portion of loose clot was detached and found its way through carotid. Deaths in the second class of cases he attributed to heart strain through limitation of the pulmonary circulation. The heart was strained against a very serious obstruction in the arterial field through the right ventricle. The operation was to relieve pressure by dilating the vessels as much as possible; for this purpose amyl nitrite was obviously the most valuable drug. In embolism or infarction the first symptom was invariably pain, and the temperature did not go up until afterwards; in this respect it was different from pneumonia, where the pyrexia came first, and the dyspnoea was a comparatively late symptom. He believed that it was to thrombosis of the pulmonary veins that they must look for the source of the cerebral emboli which formed quite a large proportion of these cases. There was a very prevalent belief that embolism was due to sepsis, but this he could not entirely endorse; the majority of cases in which pulmonary embolism occurred were cases in which there was no evidence of sepsis at all. The exact morbid pathology was not clear, but he thought it evident that a degree of stasis in the veins or at least a sluggish circulation must be present before vascular clotting could take place. The fact that such embolisms did not occur after operation on children was further evidence in support of his view. But while a considerable degree of venous stasis was a necessary factor in post-operative thrombosis, it was not the only factor, otherwise mere recumbency or lack of movement, without any operation at all, might result in thrombosis. In his view, before intravascular clotting could occur, two factors must be present: (1) a certain amount of thrombokinase derived from the tissues of the body and liberated into the blood by the wound, and (2) venous stasis. Neither factor alone could produce thrombosis. The condition was not one which lent itself to treatment; the hope lay in means of prevention. Such steps as were possible must be taken to prevent venous stasis in the branches of the vena cava. The preliminary purgation of the patient should be abandoned entirely, or, if necessary at all, should be carried out five or six days before operation. Starvation before and after operation should be relegated to the pages of history. Care must be taken to avoid as far as possible any constrained position on the operation table, and after operation the patient should be encouraged to move or should be moved so that the larger muscle masses were brought into action.

Mr. VIEROR BONNEY believed that pulmonary embolism was the result of sepsis, but the word must be understood in a very wide sense, and the condition presented some peculiar and obscure features. In the greater number of gynaecological cases, and also in cases of ordinary labour, it occurred, if at all, between the tenth and twentieth day following operation or delivery, and this was the period in which other complications most frequently occurred. In nearly all cases in which pulmonary embolism eventuated, whether after a gynaecological operation or after labour, the progress of the patient up to that point had been satisfactory, and the gynaecologist or obstetrician in charge was inclined to feel aggrieved at the occurrence of the embolism. But, as a rule, if the temperature chart were examined it would show that these patients were not quite right; the temperature might perhaps have gone up to 99° F. every evening for a week, or there might have been what he called subnormal fever. Pulmonary embolism was of most common occurrence after operations on the uterus. Among 1,791 hysterectomies performed at the Chelsea Hospital for Women from 1905 to 1918 it occurred five times. The incidence was much smaller in operations on the ovaries and tubes. In hysterectomy both the ovarian and the uterine veins were interfered with; in other gynaecological operations the ovarian only, or perhaps neither of the trunk veins. The uterine veins were very irregular, often lying below or in front of the uterine artery. So far as he knew, there were no valves in that uterine system of veins. In a pregnant uterus the conditions were somewhat modified, because then the trunk system of veins was extended into the uterus itself, whereas in the non-pregnant uterus the trunk veins ceased on reaching the uterine wall. He thought it probable that there was some auto-infection of the veins, occurring between the tenth and twentieth day. Whatever the nature of this infection,

whether by bacteria or toxins, the injury to the vein wall was very slight, and the resulting thrombus was very feebly attached; so that it was easily separated. He questioned Mr. Lockhart-Mummery's statement that these cases were increasing. At the Chelsea Hospital for Women, while there had been, as he had said, five fatal cases due to this cause out of 1,791 hysterectomies from 1905 to 1918, if an earlier period were taken, from 1895, out of 1,573 hysterectomies the deaths from this cause numbered eleven; if all operations on the abdomen performed at this hospital were taken, the incidence of pulmonary embolism in the earlier period was again about twice what it was in the later. He could not think of any difference in operative technique to explain this, although certainly the operations were now done more dexterously and expeditiously, and no doubt sepsis was much lessened and recovery more rapid.

Dr. ARTHUR LATHAM thought that the bulk of cases of pulmonary infarction were not correctly diagnosed even at the present day. They were diagnosed as pneumonia or pleurisy, or it was frankly stated that the case was not understood. In the majority of cases, unless death occurred at once, the patient did well. The only necessity with regard to treatment was complete quiet and the avoidance of meddling tactics. His experience was that most of the cases of pulmonary infarction occurred in people who were run down or were in a chronic debilitated condition. In treatment he made a practice of giving citric acid in considerable doses, and believed that it had some effect in diminishing the tendency to thrombosis. The acid itself should be given, not citrates, which were inert.

Sir CHARLES GORDON-WATSON said that in 1921, in his wards at St. Bartholomew's, he lost two patients from pulmonary embolism after operation, and he had three cases of pulmonary infarction which recovered. He had asked Dr. Spilsbury to look through the *post-mortem* records of two years, and it was found that in those two years, out of 1,013 consecutive necropsies, the deaths from pulmonary embolism numbered nine, and Dr. Spilsbury rather thought there was one other case which was not indexed, making this the cause of 1 per cent. of the deaths. In the gynaecological department of Johns Hopkins Hospital, among 21,000 operations there were 31 deaths attributed to pulmonary embolism. He believed that it was a great mistake to purge the patient beforehand. The loss of fluid in the blood by purging, the haemorrhage during operation, and the post-anaesthetic vomiting, were all factors which the surgeon could minimize. Among other contributory factors were a recumbent position and diminution of respiratory effort and muscular contraction, together with any factor which caused clot. In his wards a scheme of respiratory exercises was carried out by patients after abdominal operations, and massage was also given where possible. He could not help thinking that posture played some part in the trauma of the vessels. In the records of the Mayo Clinic the frequency of cases of thrombosis was greatest, next after operations on the uterus, in gall bladder operations, and it was in these operations that the spine was screwed up in such a way that the inferior vena cava must be stretched to a very considerable extent. Cases of pulmonary infarction seemed to be on a different basis from cases of sudden pulmonary embolism. Most of the former did show an irregularity of temperature after operation, and did not run a normal course. Of the two cases which died in his wards last year, one was a gall bladder operation, and the thrombosis was found, not, as might have been expected, in the inferior vena cava or its branches in the pelvis, but in the superior vena cava right up in the innominate, involving the right innominate and to some extent the left. The other was a breast case, and no thrombosis was found at all.

Dr. J. BLONFIELD, who was invited to speak as an anaesthetist, claimed that most of the so-called other pneumonias were simply pulmonary infarctions. He believed that the effect of any of the commonly used anaesthetics on the clotting power of the blood was negligible. With regard to post-anaesthetic vomiting as a contributory factor to clotting, he thought it might fairly be claimed that this vomiting had greatly decreased in modern practice. Patients were much better off in this respect than they were twenty years ago.

Mr. W. McADAM ECCLES said that he had had three cases of pulmonary embolism in six weeks recently. Two of these cases were fractures, and the possibility was suggested to his mind that in many of these cases of embolism after operation the conditions were similar to those obtaining in a fracture—

namely, there was injury to the vessels and injury to the fatty tissue. It might be that clot causing pulmonary embolism in some way resulted from this combination. Both these cases were comminuted fractures opening up a good deal of medullary tissue, but there was no wound, and consequently sepsis was not to be expected. There was no rise of temperature in either case. The third was an operation case—a case of hernia in a very stout man, who was getting up a fortnight after operation when he suddenly died.

The President remarked that there appeared to be few, if any, cases of pulmonary embolism recorded in war surgery. Partly this might be explained by the good physical condition of the patients and partly by the fact that they were not burdened with over-preparation for operation. His own opinion was that these cases were not increasing; figures which suggested that they were on the increase might be the result simply of the more careful investigation and analysis of cases which now obtained.

Mr. LOCKHART-MUMFELY, in reply, said he felt no doubt that dyspnoea in pulmonary embolism was due to the tremendous strain thrown upon the right ventricle of the heart in trying to force the blood through the blocked pulmonary artery. He had made inquiries in various directions about these conditions in war casualties, and the universal opinion was that pulmonary embolism was exceedingly rare in war surgery, if it existed at all. The vigorous circulation of the men and the fact that they were not kept so still as the ordinary hospital case might go far to account for the immunity.

BRITISH ORTHOPAEDIC ASSOCIATION.

THE annual meeting of the British Orthopaedic Association was held at Liverpool on December 2nd and 3rd, 1921, under the presidency of Sir ROBERT JONES.

Late Results of Treatment of Congenital Dislocation of the Hip.

Mr. H. A. T. FAIRBANK, in opening this discussion, presented a survey of the late results in a personal series of 145 cases (175 hip joints) examined at least five years after the attempted reduction of the dislocation. He divided his cases into three age groups—(a) under 3, (b) 3 years and over but under 6, and (c) 6 years and over. The results were tabulated in three categories—namely, cures (first class and second class), anterior repositions, and failures. In his experience cases seen before the end of the third year offered the chance of obtaining by manipulative reduction 70 per cent. of cures in unilateral cases and 50 per cent. in bilateral cases. In a small group of cases giving imperfect results from the manipulative method he advised an open operation, the object of which was the making of an upper lip for the acetabulum without opening the joint. He considered that open reduction of the dislocation was always unnecessary in the younger ages, but was justified in those cases of the middle age group in which manipulative reduction had failed. He believed that anterior repositions rarely gave functional results superior to those seen in untreated cases, but he considered it on this point further information was urgently needed. In general, Mr. Fairbank had found that the anatomical (as judged from radiograms) and the functional results showed a parallelism. He dealt with some of the complications arising from reduction—for example, arthritis, pseudo-coxalgia, ankylosis—and he instanced how the imperfect hips of congenital dislocations were liable to secondary ages. In the routine manipulative treatment he emphasized the importance of maintaining the position of full extension for a minimum period of six months. A considerable number of lantern slides illustrating the radiographic results were shown.

E. LAMING EVANS, in continuing the presentation of subject, also based his conclusions on an investigation of a similar series of cases. He made a plea for the treatment of congenital dislocation at an early age, and in this was in accord with Mr. Fairbank. Mr. Laming Evans considered, however, that the majority of cases the patients after anterior reposition had good function, and that the results were to be preferred to those of untreated cases.

Sacralization of the Fifth Lumbar Vertebra.

W. THURSTAN HOWLAND, in a short paper, pointed out the attention had been directed to sacralization of the fifth lumbar vertebra in this country, although in

America and Continental surgical and radiological literature numerous papers were available. As a radiologist he had observed a number of examples of this anomaly, either in the routine examination of suspected renal conditions or where symptoms had been definitely localized to the lumbosacral region. He described one case in which removal of an abnormal transverse process of the fifth lumbar vertebra had produced relief of the chronic backache.

In the discussion following this paper the President and others gave instances in which the operative removal of such abnormal transverse processes had been followed by the relief of previous symptoms, but the consensus of opinion was that such operations were to be advised with extreme caution.

Endosteal Tumours.

Mr. HARRY PLATT read a short paper on a small series of endosteal tumours of the long bones which illustrated certain points: (1) The healing of a myeloma after curettage; (2) the occasional necessity for amputation for a myeloma; (3) the rapid visceral metastasis in this sarcoma following amputation; and (4) the simulation of a primary neoplasm by an apparently solitary endosteal tumour of the tibia, which proved to be of an epithelial type, and secondary to a probable malignant tumour of the kidney or adrenal.

Demonstration of Patients and Operations.

At the Royal Southern Hospital (Orthopaedic Service) on December 2nd Mr. T. R. W. ASHORN showed a number of patients illustrating in particular some very successful results of bone grafting for flail joints. Following this a number of operations were performed.

On December 3rd Mr. R. C. ELMSLEY showed a series of lantern slides illustrating various types of fibro-cystic disease of bones and other cystic conditions. He pointed out the importance of establishing clinical groups, in dealing with such comparatively rare conditions falling into various pathological categories.

MIDLAND OBSTETRICAL AND GYNAECOLOGICAL SOCIETY.

THE first ordinary meeting of the Midland Obstetrical and Gynaecological Society was held at Bristol University on December 6th, with the President, Professor EWEN MACLEAN, in the chair.

Professor WALKER HALL gave an account of his research on the part played by different dilute acids in septic infections, and showed how careful determinations of hydrogen ion concentration were of value in accelerating and retarding growth of micro organisms. In the making of blood cultures, and in connexion with developments in some aspects of diphtheria and tuberculous infection.

Professor WALTER SWANN reported a case of fibromyoma of the uterus complicating pregnancy and necessitating hysterectomy, and showed microscopic sections of the uterine wall from a case of accidental haemorrhage, partially concealed, associated with toxæmia. The sections showed interstitial haemorrhages and degeneration.

THE PRESIDENT showed a specimen from a case of hypernephroma of the right kidney presenting some features of interest; on abdominal examination the case had presented many of the physical properties of a right ovarian tumour, and the patient had shown no sign of any suprarenal virilism. Dr. MACLEAN also showed a specimen of a large fibromyoma of the cervix uteri removed by panhysterectomy, and commented on the operative difficulties.

Mr. CHRISTOPHER MARTIN and Mr. FURNEAU JORDAN, speaking of this case, both favoured enucleation of the fibroid prior to removal of the uterus.

Dr. G. I. STRACHAN showed a case of micrencephaly, which presented the typical retroflexed head and large foramen magnum, but no spina bifida. The specimen also showed absence of the left cupula of the diaphragm and numerous other abnormalities. Dr. Strachan also showed a specimen of thoracophagous twins united in the sternal and abdominal regions, and showing a large umbilical hernia, with single cord, in the line of fusion. The left twin showed absence of the left fibula and gross deformities of the left hand.

Dr. R. T. CARR showed specimens from the *post-mortem* examination of a case of acute haemorrhagic suprarenalitis occurring in a woman eight months pregnant. She had presented all the symptoms of acute intestinal obstruction, but on operating no mechanical obstruction was found. The right suprarenal body was very much enlarged and haemorrhagic, and the left similarly affected but to a less degree.

Reviews.

ATHLETIC TRAINING.

How to Become an Efficient Athlete, by Dr. JOHN B. McDougall, is a book which should be studied by every young man who may aspire to do well at any athletic game or sport; if read and thoroughly digested by many of those persons who call themselves "trainers" it will do much to make their work more effectual and beneficial to those under their care. In an excellent introductory chapter Dr. McDougall points out the haphazard methods of training adopted, not only by the novice who attempts to prepare himself, but also by those whose vocation it is to supervise the work of "valuable" professional football players. He gives excellent advice, has a timely tilt at the bogey of "athlete's heart," and points out that which should be the real aim and object of scientific training and preparation, and what true "fitness" should mean.

The physiology of the heart, lungs, and muscles in their relation to training is shortly and clearly dealt with in language to be "understood of the people." It is made quite clear that men in training are individuals, and that the methods of the bed of Procrustes cannot in any way succeed. Some men are "gluttons for work," and require it; for others a much milder régime will suffice, and any over-pressing will quickly result in staleness. There is a chapter on the skin and its most important functions during hard physical exercise, with directions as to the proper use of baths and massage, and a much-needed warning against "dilly-dally" on the training ground. Accidents and injuries, with their causes, are discussed, and in the chapter on diet the vexed question of the use of alcohol and tobacco during training is fully argued. The book concludes by setting forth the necessity for a broad view on athletics generally; this section should be carefully studied by parents, guardians, and schoolmasters generally. In the next edition a few words might be introduced on the special work required to get fit for cycle racing, for this sport differs from football and running (so ably dealt with in this work) in that the weight of the body is carried on wheels, and not on the feet. An extra word of warning to old athletes who may attempt to compete or play a strenuous game without very adequate preparation after cessation from active participation for some time would by no means be out of place. One other observation may be hazarded: it is that the ordinary club-playing amateur can hardly obtain the ideal preparation necessary for first-class and professional excellence, and perhaps does not need it. In the seventies of the last century a run across Hyde Park to early morning lecture was sufficient to ensure fitness enough to last through two strenuous "forty-fives" in international Rugby matches.

SURGERY OF THE UPPER ABDOMEN.

It is well to make a virtue of necessity. One of the most satisfactory surgical textbooks published of late years, *Surgery of the Upper Abdomen*,² by DEEVER and ASHURST, had the added attraction of convenient size, dignified page, admirable type, and everything that goes to the making of a real "book." And now—although

"Surgeon nobis despise all jobs,
Utility that verge on"—

here are the authors of a second edition writing a whole page of preface to prove that one volume without bibliographies, with summarized and condensed tables, and smaller margins, is better than two delightful volumes. Of course they are right, especially when, with all their sacrifices, the present edition costs £3 10s. The book is so well known and so constantly in use by surgeons that it is unnecessary to do more than mention some of the additions and revisions.

The section on gastric ulcer has been rewritten, with a new description of the stomach and its physiological "arcas"; a new discussion of gastric analysis, and incidentally a new figure of sites of perforation of gastric ulcers, which is an extraordinary divergence from the analogous picture in the

old edition. It certainly accords more nearly with average surgical experience. The junior author, it seems, reading between the lines, has had charge of this edition, but he preserves the same cautious non-committal attitude where he has not good personal grounds for a preference. On the question of "excision" of ulcers by the transgastric or other routes he has an open mind, whilst against "occlusion of the pylorus" he is almost decided, and for "partial gastrectomy" he certainly has a hankering, in preference to all tinkering methods.

For infantile stenosis Rammstedt's operation—simple incision down to the mucosa—is his choice. The discussion of jejunal and gastro-jejunal ulcers after gastro-enterostomy is interesting and charitable, though he still thinks an unabsorbable suture in the mucosa a sin. The sections on operative surgery of the gall bladder and spleen have similarly been revised, and there is a new section on operative removal of the descending duodenum.

The book, in its compact singleness of volume, remains a storehouse of practical information—a veritable surgeon's guide, philosopher, and friend.

INFLUENZA.

In his *Studies in Influenza*,³ Dr. BARTY KING first gives an account of an outbreak of 71 cases among 150 patients with malaria coming from Salonica and admitted to the County of London (Horton) War Hospital, Epsom, in September, 1918. Eight of the 71 patients died, and of these 7 had acute bronchopneumonia and 1 acute lobar pneumonia. It was noted that while quinine rapidly cured non-influenzal bronchitis in malaria patients, the continuous administration of quinine in cases of influenza in malarial subjects with acute pneumonia as a complication with no active malaria was harmful. Isolation, absolute rest in bed, and the early administration of streptanthins in large doses, were found to be the best lines of treatment in such cases. The author's second study deals with the after-effects of the acute pulmonary complications of influenza; here the use of the x-rays in diagnosis is particularly recommended.

The third study gives an account of the incidence of influenza among the nurses and maids on the hospital staff during the influenza epidemic of 1918-1919. Among the 329 nurses 84 caught influenza and 2 died; both these nurses contracted the infection while nursing a severe case of influenza with acute bronchopneumonia, while a third nurse after five days' contact with the same case contracted a severe type of influenza that nearly proved fatal, the resident aural surgeon, treating the patient at the beginning of his illness, died of acute septic pharyngitis and septicaemia and the chaplain, who was in contact with the patient throughout, contracted influenza with bronchopneumonia and died. It appeared that all the nurses developing severe forms of influenza had been working in wards containing severe cases of influenza, but that the incidence of influenza among the nurses was the same whether they had been in contact with mild or with severe cases. Dr. Barty King's book contains a great deal of valuable information on the symptoms and epidemiology of influenza; it will be read with particular interest at the present time when the disease appears to be on the move again in London and other great towns.

QUALITATIVE CHEMICAL ANALYSIS.

The chemist who is much occupied with intricate analysis needs a reference book of wider range and more extensive detail than the textbook from which he learnt his first principles. Among the books which fulfilled this need with an older generation of analysts were those of C. REMIGIUS FRESENIUS on qualitative and quantitative analysis. TH. WILHELM FRESENIUS has produced a seventeenth edition of the original work by the first Fresenius, and a translation of it by C. AINSWORTH MITCHELL, with the title, *Introduction to Qualitative Chemical Analysis*,⁴ has been issued.

The opening chapters deal with fundamental conceptions of chemistry; then follow descriptions of the various operative methods potentially serviceable to analytical aims; next are

¹ *How to Become an Efficient Athlete*. By John B. McDougall, M.D. Glasg., M.R.C.P. Edin., F.R.F.P.S. Glasg., London: Henry Kimpton, 1922. (Cr. 8vo., pp. 58; 20 figures, 2s. 6d. net.)

² *Surgery of the Upper Abdomen*. By J. B. Deever, M.D., Sc.D., LL.D., F.A.C.S., and A. P. C. Ashurst, A.B., M.D., F.A.C.S. Second edition. Philadelphia: P. Blakiston's Son and Co., London: H. K. Lewis and Co., Ltd., 1921. (Roy. 8vo., pp. 849; 198 figures, 9 plates. £3 10s. net.)

³ *Studies in Influenza and its Pulmonary Complications*. By D. Barty King, O.B.E., M.A., M.D. Edin., M.R.C.P. Lond., and Edin., 1921. (Demy. 8vo., pp. vi+88; 31 figs., 7s. 6d. net.)

⁴ *Introduction to Qualitative Chemical Analysis*. By Th. W. Fresenius. Seventeenth edition of the original work by C. Remigius Fresenius, translated by C. Ainsworth Mitchell, M.A. Oxon., F.I.C. London: J. and A. Churchill, 1921. (Demy 8vo., pp. 961; 57 figures, 36s. net.)

described the properties and reactions of elements, cations and anions; and finally are given schemes for the detection and recognition of the same elements and ions in complex mixtures. There are special chapters treating of the analysis of mineral waters and soils, and detailing processes designed for toxicological investigation; an appendix treats of vegetable alkaloids and toxic principles.

The sequence of arrangement and the style of presentation are substantially the same as in former editions, but descriptive terms are altered to agree with modern conceptions of chemistry: the new matter consists chiefly of accounts of useful reactions which were unknown when the last edition was issued. Chemists who are familiar with former editions will be well satisfied with the continuation in the new volume of the former scheme of presentation, which fulfils their needs very well. The descriptions of principles and methods relating to analytical reactions are complete and instructive, and the schemes detailed for separation of the constituents of mixtures are excellent examples of chemical procedure. The volume contains all the information that analysts may be expected to need regarding inorganic materials and the organic substances of ordinary occurrence.

The articles treating of mineral waters, soils, and toxicological investigations hardly differ from those of former editions. Such a process as that given for the elimination of arsenic from body tissues, which is one of most elaborate procedure, would rarely be adopted in the present day, but its inclusion seems nevertheless to be proper to the character of the book as an example of exact method. The part which deals with the isolation and identification of alkaloids is educational in the fullest degree. The solubility tables given have a certain measure of usefulness, and the coloured spectra of elements from the older volume is reproduced in the new.

Unstinted praise cannot be given to the translation. Signs are numerous that care was lacking in the choice of English expressions. The phrase (page 58), "the absolutely dry mixture of the substance and the explosive agent . . ." is less pleasing than the corresponding expression in the former English translation, which reads (page 15), "the perfectly dry mixture of the substance with the deflagrating agent. . .". Deflagration is explained and described as "explosive fusion" (page 58); in some cases the text retains the guise of the original German, as in the sentence (page 279), "when the ammonia was added in excess these precipitates consist of . . ." On page 230 "ductible" is used for ductile, and on page 15, "The identification of these substances to be investigated by analytical analysis may be effected . . ." It may be judged from these instances that some of the paragraphs treating of general chemical principles and fundamental conceptions of chemistry are lacking in the lucidity which is so important to younger students. Nevertheless, the quality of the book as a trustworthy guide in all those problems in which the analyst may have occasion to employ unusual methods is well maintained. Very few typographical errors have been noted, but the index might with advantage have been much more extensive.

PHOTOGRAPHY.

THE *British Journal Photographic Almanac* for 1922,¹ edited by GEORGE E. BROWN, contains, in a condensed form, such a vast amount of information on everything photographic that it is almost indispensable as a reference book to any photographer, amateur or professional. The trade advertisements alone take up some 450 pages, and practically everything used in photography is referred to; a feature of this part of the volume is the illustrations. The main portion of the text deals with photographic societies and various photographic bodies; there is an article on "self-instruction" by the editor; and following this is an epitome of progress. Events of the year, apparatus and equipment, negative and printing processes, and colour photography, form the subject matter of various chapters; there is also a large amount of miscellaneous information on formulae, and chemical, exposure, and optical tables are provided. One of the most interesting chapters is that on the process of desensitizing exposed plates so as to allow of their development in white light, or in a very much brighter non-actinic light than could otherwise be used. A full account of this work, which is a notable new departure in

photographic practice, is given, and the researches of Dr. Lilippo-Cramer, explaining the principles of the process, are related. The exposed plate is soaked in a red dye solution before development, and it is interesting to note that this dye does not merely act as a screen, but has in addition a direct desensitizing effect. The method should be of great practical use in the development of panchromatic plates. Valuable and complete indices complete the book.

NOTES ON BOOKS.

THE exhaustion of two editions of Dr. J. S. FAIRBAIRN'S *Textbook for Midwives*,² and the appearance of a third in the space of seven years, indicates that it has found an appreciative public. By this we are not surprised, for the book bears throughout the stamp of the careful and practical teacher. In the present edition the only changes of note are in the section dealing with the infant, which has been rewritten and brought quite up to date. We have no doubt that this edition will soon be followed by successors. It is a book that we can unhesitatingly recommend to all nurses studying for the examination of the Central Midwives Board.

The second edition of Professor RICHARDSON'S book on *The Emission of Electricity from Hot Bodies*³ deals with the abstract and scientific aspects of a subject that has practical applications in wireless telegraphy, telephony, the production of X rays, and the rectification of alternating electric currents. These topics the author does not pretend to deal with; his chapters are occupied with the emission of electrons and of ions from hot bodies, and its effects. The book is one for students of physics; it gives a clear account of the subject, and is written without undue emphasis on its mathematics.

In his pamphlet on the sequelae of dysentery⁴ Professor STRAUSS of Berlin points out that these sequelae—namely, diarrhoea with or without melaena, fever and dyspepsia, and recurrent abdominal pain or colic—are in general very obstinate. Vaccine therapy, drugs, enemata, and treatment applied through the endoscope all give disappointing results; those obtained by surgical interference (appendicostomy, caecostomy) are, as he shows by quotations from the literature, not much better. His final conclusion is that prevention is better than cure, which is as much as to say that it is impossible to treat cases of dysentery with too great care and thoroughness at the outset.

A popular book on *Vitamines*,⁵ by B. HARROW, Ph.D., affords the general reader an opportunity of becoming acquainted with a subject of great importance to every man, woman and child in the civilized world. Vitamins, or accessory food factors, are essential constituents of any diet that is not to impair the health; how it came to be found that they are necessary to life is explained by the author of this book in simple language and full detail. The first half of the volume is taken up with a popular account of foods and diets generally, stress being laid on the quantities of the different classes of foods required by human beings, and on their energy content. The second half is devoted to vitamins. Dr. Harrow goes fully into their connexion with growth, and with the diseases beri-beri, rickets, scurvy, and pellagra. At the end of his volume he gives a number of references to the literature of the subject. Dr. Harrow writes incisively, and has produced a very lucid account of a difficult but highly important subject.

The late Dr. GEORGE HERSCHELL'S *Cookery for Dyspeptics*⁶ is an excellent, brief, and thoroughly practical volume for the friends and cooks of dyspeptic patients to use, because, as the author points out, it is they rather than the medical attendant who will in fact settle what the patient eats. Beginning with recipes for the preparation of liquid foods, the author gives directions for soups, purées, semi-solid and solid foods in succession. No lists of foods for different ailments and no diet tables are given. Dyspepsia, both declared and unrecognized, is so common nowadays that this serviceable little manual should prove widely useful.

¹ *A Textbook for Midwives*. By John S. Fairbairn, M.A., B.M., B.Ch. Oxon., F.R.C.P. Lond., F.R.C.S. Eng. Third edition. Oxford Medical Publications. London: Henry Frowde, Hodder and Stoughton, 1921. (Roy. 8vo. pp. xiii + 365; 113 figures, 3 plates. 25s. net.)

² *The Emission of Electricity from Hot Bodies*. By O. W. Richardson, F.R.S. Second edition. Monographs on Physics. London and New York: Longmans Green, and Co., 1921. (Med. 8vo. pp. 323; 34 figures. 15s. net.)

³ *Nachkrankheiten de Ruhr*. Von Professor Dr. H. Strauss. Halle a. S.: C. Merhold. . . . 6 figures. M.T.)

⁴ *Vitamines*. . . . By B. Harrow, Ph.D. London: G. Routledge . . . 8vo. pp. 229; 8 charts. 10s. 6d. net.)

⁵ *Cookery for Dyspeptics*. By the late Dr. G. Herschell. London: E. Arnold. 1920. (Demy 8vo. pp. 56. 2s. 6d. net.)

⁶ *The British Journal Photographic Almanac and Photographer's Daily Companion, 1922*. Edited by George E. Brown, F.I.C. London: Henry Greenwood and Co., Ltd. (Cr. 8vo. pp. 813; illustrated. Paper cover, 2s.; cloth, 3s. net.)

*The Rights of the Ex-Service Man and Woman*¹¹ is primarily a handbook for the use of those in need of information for practical purposes. As such it may be recommended; it is comprehensive in scope, accurate in detail, and adequately indexed. Mr. SHERRER has, however, adopted the historical form, and in doing so has given his work a more general interest, as it affords a concise review of the genesis and evolution of a sense of social responsibility unique in history, and its practical issue in the development of an extraordinarily complete system of administrative machinery. The preface, by Mr. C. A. McCurdy, M.P., serves to focus attention on the main features of that development.

The eighth edition of Professor JOSEPH'S textbook of venereal diseases¹² gives a good account of current German practice in the symptomatology, diagnosis, and treatment of syphilis, soft sore and gonorrhoea. It is a practical work, not too long, but rather badly illustrated. If anyone in this country thinks of ordering it he should ascertain beforehand what he will be asked to pay.

Erratum.—We regret that, through a clerical error, it was stated in a footnote to our review of Emerson's *Clinical Diagnosis* last week (p. 18), that the publishers of this work are William Heinemann (Medical Books), Ltd., whereas the publishers in fact are J. B. Lippincott Company, Philadelphia and London.

¹² *Lehrbuch der Geschlechtskrankheiten; für Aerzte und Studierende*. By M. Joseph. Eighth edition. Leipzig: G. Thieme. 1921. (Sup. roy. 8vo, pp. 217; 54 figures, 1 plate. M.54; bound, M.68.)

MEDICAL AND SURGICAL APPLIANCES.

Instrument for the Treatment of Haemorrhoids by Suture.

Dr. JAMES MACMUNN (London, E.C.) writes: To cause a wound to heal by first intention rather than by the slow method of granulation (ligature method) is sure y more surgical, and it is chiefly to ensure quick union and to guard against sepsis that I wish to bring the present method for the treatment of haemorrhoids by suture into notice. The forceps illustrated is a modification of Ricard's phimosia forceps, but the slot is much smaller, allowing only the passage of a small domestic needle. It is also open at the end. A is an enlarged section showing how the tissues are com-

pressed above and below the slot for suture. The on the pile in the gut axis and the pile lifted by a pile forceps before clamping. The pile is suture, anointed with bipp, is used as shown in the lower part of the illustration; B embraces the pile supplying artery. Very little sustaining power is required by the suture to keep the tissues together; they are pressed into apposition and bipp is rubbed over the part. The instrument is made for me from my model by the Holborn Surgical Instrument Company.

A Self-Retaining Vaginal Retractor.

Mr. B. K. TENISON COLLINS (Cardiff) writes: This retractor has been designed to dispense with side retractors held by assistants. It can be used by itself or in conjunction with an Anvard speculum.

When in position with the spring above, the blades lie parallel and do not squeeze out. It is quite out of the way of the operator, and gives a good view of the cervix and vaginal fornices. It protects the vaginal walls, is cheap to make, easy to clean, has no loose pieces, sharp angles or points, and takes up little room in the instrument bag. I have used it now for some time, and find it very useful. It has been made

for me by Mr. Staniforth, of Cardiff, to whom I wish to express my thanks.

THE new number of the *Journal of Obstetrics and Gynaecology of the British Empire* is a double number—autumn and winter, 1921 (Manchester: Sherratt and Hughes, 24s. net). It is almost wholly devoted to a series of papers on Caesarean section. We hope to refer to the issue at length on some future occasion.

PROFESSIONAL SECRECY AND MEDICAL EVIDENCE.

BY

WILLIAM A. BREND, M.D. LOND.,

Lecturer on Forensic Medicine, Charing Cross Hospital Medical School.

THE ruling, first given by Lord Mansfield at the trial of the Duchess of Kingston for bigamy in 1776, and at later dates repeated by other judges, that a medical man has no privilege to avoid giving evidence on the ground that his knowledge was gained in the practice of his profession, has ever since been accepted by the medical profession as the law on this subject. The issue, however, by the Ministry of Health of the Public Health (Venereal Diseases) Regulations in 1916 has led to some questioning of the hitherto recognized ruling. These regulations were made under the powers conferred on the Local Government Board by the Public Health Acts of 1875 and 1896, and the Public Health (Prevention and Treatment of Disease) Act of 1913, which authorize the Board to make, alter, and revoke regulations with a view to the treatment of persons suffering from cholera or any other infectious disease, and to make regulations for the provision of medical aid and for guarding against the spread of the disease. Article 22 of the Venereal Diseases Regulations runs as follows:

"All information obtained in regard to any person treated under a scheme approved in pursuance of this article shall be regarded as confidential."

The suggestion that this regulation affected the law relating to professional secrecy in the witness box was first made in the case of *Garner v. Garner* in January, 1920. This was an undefended divorce case in which the petitioner desired to call evidence that she had suffered from venereal disease. She had been treated under a Venereal Diseases Scheme, and before giving evidence the medical witness called the attention of the judge to it. "Professional secrecy which was imposed upon him," Mr. Justice Horridge said that in a court of justice there were even higher considerations than those which prevailed with regard to the position of medical men, and he ruled that the witness must answer the questions put to him.

The point again arose in the Divorce Court in a case heard before Mr. Justice Horridge in June, 1921. The medical witness in this case stated that he and other medical men had undertaken duties at the clinic on the distinct understanding that professional secrecy as to what happened there would be observed, and referred to Article II (2) of the Public Health (V.D.) Regulations quoted above. The judge replied that the Ministry had no powers which affected the jurisdiction of the courts, and required the witness to give evidence.

The question was fully discussed at the Annual Representative Meeting of the British Medical Association, and on July 15th, 1921, the following resolution was passed:

"That the Association use all its power to support a member of the British Medical Association who refuses to divulge without the patient's consent information obtained in the exercise of his professional duties, except where it is already provided by Act of Parliament that he must do so."

Lord Dawson gave notice to call attention, in the House of Lords on July 27th, "to recent rulings as to the privilege of medical men with regard to evidence in courts of justice; and to move that the matter be referred to a Select Committee of the two Houses of Parliament." At the request of the Government, he agreed at the last moment to postpone the motion. At the time of writing, the notice of motion still remains on the Order paper of the House of Lords, but no opportunity of moving has occurred.

It may be stated at once that there is no doubt that the rulings given by Mr. Justice McCardie and Mr. Justice Horridge are sound law, and that the regulations issued by the Ministry of Health do not override or modify the law of evidence. This is in conformity with the general principle that when in an Act of Parliament the details of any procedure are left to be settled by regulations made by an administrative authority, it is implied that these regulations must be in conformity with the principles laid down in the Act or in other Acts, or established at Common Law. In so far as any regulations made by the administering authority infringe the law, they are *ultra vires* and of no effect. In the actual instance there is no reason to suppose that those who framed Article II (2) of the Regulations did intend that

it should apply to medical evidence in the witness box. The word "privilege" is not used, and it must be assumed that if the Local Government Board had intended to upset a recognized legal principle it would have made its position clear. On the other hand, the apparent comprehensiveness of the regulation fully justified the medical witnesses in making protest before giving evidence.

The view that privilege should exist between doctor and patient in the witness box is one which at first sight is likely to commend itself to medical men, imbued as they are with the lofty ethical traditions which govern the question of professional secrecy. Nevertheless, the recognition of such privilege would be a startling innovation in English law, and there are difficulties and objections to it which only present themselves on careful consideration of the question. Before noting these it may be useful to examine the procedure adopted in certain foreign countries and the experience gained therefrom.

The Law in the United States of America.

In America the law varies from State to State, and in about one-half of the jurisdictions professional privilege to varying degrees has been established between physician and patient. The following are instances of the State laws:

Arizona.—"A physician or surgeon cannot be examined without the consent of his patient as to any communication made by his patient with reference to any physical or supposed physical disease, or any knowledge obtained by personal examination of such patient; provided that if a person offer himself as a witness and voluntarily testify with reference to such communications, that is to be deemed a consent to the examination of such physician or surgeon."

Arkansas.—"No person authorized to practise physic or surgery shall be compelled to disclose any information which he may have acquired from his patient while attending him in a professional character, and which information was necessary to enable him to prescribe as a physician or do any act for him as a surgeon."

California.—"A licensed physician or surgeon cannot, without the consent of his patient, be examined in a civil action as to any information acquired in attending the patient which was necessary to enable him to prescribe or act for the patient—but this subdivision does not apply in an action between physician or surgeon and his patient in which the treatment of the patient by the physician or surgeon is in issue; and provided that in an action brought under Sections 376 and 377 (for death by wrongful act) a physician or surgeon is competent to testify as to the cause of death of the deceased."

New York.—"No person duly authorized to practise physic or surgery shall be required to disclose any information which he may have acquired in attending a patient in a professional character, and which information was necessary to enable him to prescribe for such patient as a physician or to enable him to do any act for him as a surgeon; provided a presiding judge of a superior court may compel such disclosure if, in his opinion, the same is necessary to a proper administration of justice."

Pennsylvania.—"No person in any civil case shall be allowed to disclose any information which he acquired . . . which shall tend to blacken the character of the patient, without his consent."

It will be seen from the foregoing that there are considerable differences in the various States, and that the privilege is more comprehensive in some than in others. We need not examine in detail the practical effects of the legislation in each State. It is sufficient to say that commentators on American law and experience do not find that the States in which medical professional privilege does not exist are at any disadvantage as compared with those where privilege has been admitted, and they consider that in the latter the system has often led to serious abuses militating against the administration of justice. Wigmore, for instance, says:

"Certain it is that the practical employment of the privilege has come to mean little but the suppression of useful truth—truth which ought to have been disclosed and would never have been suppressed for the sake of any inherent repugnancy in the medical facts involved. Nine-tenths of the litigation in which the privilege is invoked consist of actions on policies of life insurance, where the deceased's misrepresentations of his health are involved; actions for corporal injuries, where the extent of the plaintiff's injury is at issue; and testamentary actions where the testator's mental capacity is disputed. In all of these the medical testimony is absolutely needed for the purpose of learning the truth. In none of them is there any reason for the party to conceal the facts except to perpetrate a wrong on the opponent."

The Law in France.

In France, Article 378 of the Penal Code provides as follows:

"Physicians, surgeons, and others concerned with health, such as pharmaceutical chemists, midwives, and other persons, the recipients by their position or profession of secrets which have been confided to them, who, except when the law requires them

to give information, have revealed these secrets, will be punished with imprisonment from a year to six months and a fine of 100 to 500 francs."

As in this country, the law definitely requires from medical men certain professional information, such as declarations of birth or of infectious diseases, which, in the interests of the community, should be known, and in the discharge of these obligations medical men are protected by the words "except when the law requires them to give information." It is interesting to note, incidentally, that in regard to syphilis the law goes further than in this country, and that in some cases where there is risk of infection the medical man is not only absolved from secrecy, but is required to give warning to persons specially exposed to the risk. For instance, if, after attending a syphilitic infant, a medical man failed to warn a nurse of the danger, and she contracted the disease, she would be entitled to bring an action against him.

The extent to which the giving of medical evidence is regarded as one of the exceptions to the general principle depends upon certain conditions. Article 80 of the *Code d'Instruction Criminelle* requires any person summoned to appear as a witness to attend and give evidence, and a doctor, as any other citizen, is bound by this obligation. The conflict which accordingly arose between these two obligations was dealt with by a judgement of the Court de Cassation in 1845 in the following terms:

"Whereas every citizen is bound to assist the ends of justice when interrogated as a witness, no one, whatever his profession, is completely relieved of this obligation; it is not sufficient for a member of one of the professions bound to secrecy by Article 378 to claim as an excuse for not giving evidence that it was in the exercise of his profession that the material on which he is to be interrogated has come to his knowledge; but it is otherwise when the material has been confided to him under the seal of secrecy, to which he is bound in consequence of his profession."

Under this judgement, accordingly, the medical man was only relieved of the obligation of giving evidence in reference to facts which had been confided to him under the seal of secrecy, and not in reference to facts which had come to his knowledge through the exercise of his profession.

Subsequent decisions have helped to make clear what are to be regarded as facts communicated under the seal of secrecy. In 1853 a medical man, when called upon to give evidence on matters which had come to his knowledge in the exercise of his profession, replied: "I consider as confidential the reports which have brought to my knowledge the facts on which you interrogate me. I cannot therefore reply to your question." This reply was accepted.

The formula: "I consider as confidential" has been held to safeguard all the interests of the patient. To require the medical witness to state formally that there has been a confidential communication would be equivalent to stating that there has been an important secret to hide. As a matter of fact, it is now admitted that a doctor, in order to preserve silence, is under no necessity of invoking confidence. The facts which he learns by the exercise of his profession are secret by their nature.

In 1885 the Court de Cassation expressed the view that information which had been confided under the seal of secrecy, or, in default of this condition, were secrets by their nature, and the knowledge of them had been acquired by the witness in the exercise of his profession, fell within the scope of Article 378. Finally, in 1899 the Court de Cassation, in a case in which a life insurance company demanded the cancelling of a policy on the ground that the assured suffered from a malady which he had not declared, absolved a medical witness from giving evidence in the following words: "Since the fact, secret in its nature, on which Dr. X. had been called to depose, could only have come to his knowledge by reason of the treatment which he had given to his patient, he was for this reason forbidden to reveal it."

It is of interest to note that secrecy is obligatory even when the person concerned has authorized the medical man to speak. A judgement of the Court of Montpellier in 1827 lays down:

"The obligation of secrecy continues to exist even where he whom the facts concern, and who has confided them to another, demands the revelation; for the obligation prescribed by Article 378 is established in the general interest. It is only by this means (*à ce prix*) that professions, the exercise of which concerns the whole community, can secure the necessary confidence and consideration."

The court show themselves very severe in this matter. Even revelation by a medical man in the witness box of a fact which is no longer secret may still be an offence.

For instance, Dr. X. had given a certificate for placing a lunatic in an asylum. Some years later the patient, who had recovered and had been released, was seeking a divorce. Dr. X.

was called as a witness, and read and commented upon his certificate. He was convicted of a breach of professional secrecy, although the state of insanity of the husband was not a secret, since he had been confined in an asylum, and could only have been so confined under a medical certificate.

It is true that the Presidents of the Cours d'Assises do not appear always to have regarded the question in the same manner.

For example, in 1906, the President said to a medical man who refused to speak: "There is one case in which professional secrecy ought not to prevent you from speaking; it is when you, a medical man, have discovered indications of a crime." In the same year, in a case of poisoning brought before the Cours d'Assises of the Gironde, medical practitioners and consultants had refused to reply to questions put to them, even after their patient had absolved them from professional secrecy. They were severely criticized by the President, and even threatened with proceedings.

In spite of these utterances, however, it may be regarded as recognized that in France medical men can, without fear of proceedings, refuse to give evidence on matters which have come to their knowledge in the exercise of their profession. The right to maintain secrecy does not, however, exempt a medical man from appearing when he is summoned to give evidence. He can even be required to take the oath, and is absolved by declaring afterwards that the facts are such as cannot be revealed by him. In one case where a medical man refused to take the oath a fine of 100 francs was imposed.

The Essentials of Privilege.

In English law privilege is only admitted between solicitor or counsel and client. It has been stated to exist in regard to communications in the nature of confessions made to ministers of religion by members of their congregations, and particularly statements made to Roman Catholic priests in the confessional. This, however, is not the case, but in the very few instances in which the question has been raised in the courts the presiding judge has not pressed the witness to reveal the confidences made to him.

It is an established principle of English law that every member of the community must assist justice to attain its ends, and the law has only recognized privilege in the witness box where very strong reason for it exists. The legal view is that the following four fundamental conditions must be fulfilled before a privilege can be established:

- (1) Communications must originate in a confidence that they will not be disclosed;
- (2) This element of confidentiality must be essential to the full and satisfactory maintenance of the relation between the parties;
- (3) The relation must be one which, in the opinion of the community, ought to be sedulously fostered;
- (4) The injury that would result to the relation by disclosure of the communications must be greater than the benefit thereby gained for the correct disposal of litigation.

Brief consideration will show that, as regards information gained by the physician in the exercise of his profession, none of these conditions are fulfilled. With reference to (1), it is obvious that, as regards the vast majority of the communications made by patients to physicians, such as the details of the malady, state of health, effect of treatment, etc., a patient is not particularly concerned that secrecy should be observed. Nor can it be said that the absence of privilege in this country has prevented a full and satisfactory relationship between physician and patient. There is no reason to suppose that the community wishes to establish privilege between physician and patient. The experience of other countries has shown that the extremely small number of cases in which the patient gains an advantage by the existence of professional privilege do not counter-balance the injury to the whole community which arises from the fact that privilege enables material to be concealed, knowledge of which would promote the ends of justice. The argument that because privilege is recognized between solicitor and client, it should also be admitted between doctor and patient, is unsound, for it is obvious that the whole relationship between solicitor and client would fall to the ground if the client did not know that his statements would be kept secret. If privilege between solicitor and client did not exist, all that would be necessary for prosecutor, plaintiff, or defendant to do, would be to put the solicitor for the opposite party in the box and examine him on what had passed between him and his client. In this matter, accordingly, there is no analogy between the medical and the legal professions.

Conclusion.

To sum up, then, while it is admitted that under the present system in rare instances hardship to the patient

arises, and the medical man is placed in a position of embarrassment, it is not clear that the recognition of medical privilege in the witness box would be of advantage to the community as a whole. The experience of other countries shows that the privilege is often an avenue for the perpetration of an injustice, and its existence in this country would not be in accordance with the principles and traditions of English law.

MEDICAL TERMS IN THE VERNACULAR AND IN DIALECTS.

I.

AGNAIL OR HANGNAIL.

AGNAIL or hangnail is the term which in the vernacular is given to the troublesome little sliver or shred of separated skin which is found occasionally at the base of the nail in the neighbourhood of the quick. It is both sore and painful; the soreness is due to the raw tissue left by the separation of the epidermis, whilst the pain is caused by the tug which happens when the little cutaneous slip is caught by any passing object where it is still attached to the surface. Both these discomforts are soon removed by cutting the shred close off, and painting the spot with some tincture of iodine. To the operating surgeon who has to keep his hands fit, and to the manœuvre who has to make other people's hands beautiful, these hangnails are a matter of some moment: for the irritation they cause is out of all proportion to their size; they are always unsightly; and, in the case of persons who use their hands much in contact with infective materials, they may be actually dangerous.

Agnail is a sort of chameleon among words: it appears in ordinary vernacular English both as agnail and hangnail, whilst in the dialects it has the forms of angnail, angernail, nangnail, gnangnail, nengnail, nagnail (that is, an agnail), and thangnail (that is, th'agnail). Besides varying in appearance, it is also rich in synonyms, some of which reveal a certain grim or caustic humour in their construction. Thus, in Cumberland, Staffordshire, and other counties it is called a "back-friend," the word being used, one must suppose, in the sense of secret enemy. Wright, in the *English Dialect Dictionary*, gives an illuminating quotation in the words: "He had a troublesome 'back-friend' or 'agnail' at which he often bit." Another expressive name is "step-mother's blessing," which speaks, so to say, for itself. "Idle-wart," "idle-well," "idle-wheel," and "idle-back" are Lincolnshire and Northamptonshire synonyms which seem to hint a belief that these painful little tags of skin appear upon the fingers of the lazy. This use of the word "idle" brings back to memory the "idle worms," said humorously to grow in the fingers of people averse from work; and Shakespeare was probably thinking of them when (in *Romeo and Juliet*, I, iv, 64-66) he spoke of Queen Mab's wagoner as—

"a small grey-coated gnat,
Not half as big as a round little worm
Prick'd from the lazy finger of a nail."

"Fan-nail" is yet another Northamptonshire synonym, the little sliver being compared to a fan, or perhaps carrying the sense of fang or claw in it. "Nail-hag" is either a synonym or merely "agnail" inverted; "rag-nail," employed in the north of Ireland, explains itself.

The Scots equivalent is "anger-nail," but this is really a corruption of agnail devised to give a plausible meaning to the word, for in the North "to anger" signifies not only to irritate but also to inflame, and so the idea is conveyed of a nail which has become inflamed and sore. There is here, and perhaps also in "rag-nail," a perversion of the original word "agnail" by pseudo-etymology; and this change has occurred several other times in connexion with this same term. There is thus revealed a curious chapter in the history of word-forms.

To begin with, agnail is the Old English "ang-naegl," which comes from "ang," meaning compressed and therefore painful (one thinks of our everyday expression "anguish," with, however, quite a different etymology), and "naegl," a nail. Only the "nail" here intended is not that of a finger or toe (*unguis*) but a nail of iron (*clavus*). In complete accordance with this derivation, which goes back to the Old High German, the Frisian, and the Gothic, agnail had originally the meaning of a corn on the foot. Sir James Murray, in the *New English Dictionary*, gave illustrative quotations of agnail as "corn" ranging from 950 to 1783; but it is now obsolete. Not so, however, in the dialects: for

in several of the northern counties of England (for example, Cumberland and Lancashire) agnail is a corn, and in Yorkshire it is also a bunion. The association of ideas between a corn on the toe and a nail being driven into the flesh does not call for elaborate justification. "Nangnail salve" is a black resinous ointment sold to the afflicted for the cure of corns in sundry parts of the country.

The next change in the meaning of agnail was due to the "nail" part of it coming to be referred to the nail of a finger or toe; and so it came to signify any painful swelling, ulcer, or sore in the neighbourhood of the finger or toe, and especially a whitlow. Curiously enough Johnson in his *Dictionary* gave "a disease of the nails, a whitlow, an inflammation round the nails," as the only meanings of agnail; and he did not illustrate its use. Pseudo-etymology is surely at work again here; but a question arises as to the form it has taken. Nail misinterpreted obviously played its part in drawing attention to the fingers, but Sir James Murray thinks that a confusion with the French "angonailles," botches, bumps, or sores, or the mediæval Latin "anghiones, anginialia," earbunions, may have fixed the pathological nature of the swelling. Further confusion was introduced when agnail came to be collated in the dictionaries with the Greek *παρονυχία*, a whitlow; *παρ* was "beside" and *νύχ*, a "nail," and so "ag-" meant "at," and "nail" explained itself, giving whitlow! The Scots, too, with their "anger-nail" (inflamed nail) would come in here to confound confusion. No wonder Bailey's *Dictionary* in 1721 defined agnail as "a sore at the root of the nail," and as "a sore slip of skin at the root of a nail" in editions later than 1737; for there seemed to be no restricting the sense of the word at all. Why not search for another plausible etymology in "hang-nail"—for example, something hanging from a nail?

In this way the usual present-day meaning of agnail is reached, although it still may be employed for whitlow, and is so employed dialectally in Cornwall. The Sydenham Society's *Lexicon* (1879) defined the word in this modern sense: "agnail, a term applied to the shreds of epidermis which separate from the skin covering the root of the nail, and which, on being torn, give rise to a painful state of the fingers." So there have been at least three senses in which the word has been used. An interesting sidelight is thrown on the confusion which existed in the seventeenth and

eighteenth centuries by regarding to this word by consulting the dictionaries of Littleton and Ormerod (1678) agnail appears with two meanings: the first is "a corn growing upon the toes, *clavus pedis, paronygium*"; and the second is "a sore between the finger and nail, *paronychia*." It is, however, to be observed that the third or present-day meaning is here concealed under the Latin term *paronygium*, for in the other portion of the *Dictionary* it is defined as "the going away of the flesh from the nail with great pain." Holyoke (1677) gave only the one meaning of "a corn growing upon the toes," but he entered two Latin words, *clavus* and *callus*, still further broadening the meaning. Gaseoigne, in the lines prefixed by him to the *Art of Venerie* (1575), was also in some doubt as to the precise meaning of agnail, for in rhyming of the virtues of corns (horns) as medicines, he wrote as follows:

"As first, they heal the head from turning of the brain;
A dram thereof in powder drunk doth quickly ease the pain.
They skin a kybed heel, they fret an angnyale off;
So thus I skip from top to toe, yet neither scorn nor scoff.
They comfort fever's faint and lingering long disease:
Distill'd when they be tender buds, they sundry griefs appease.

They poison do expell from Kaiser, King, and Queen,
When it by chance or deep deceit is swallow'd up unseene."

It is evident, therefore, from what has been said that the meanings given to the words agnails or hangnails have mainly flowed in three channels. At first they were synonymous with corns, but this channel is now practically dry so far as the ordinary vernacular is concerned, and only a small trickle from the dialects passes along it. Then they had the significance of painful swellings or sores near the nails, and a considerable current ran along this second channel of meaning, and, indeed, still runs both in the vernacular and in the dialects. But the chief current is found in the third channel; agnails or hangnails now are regarded as little painful shreds of torn epidermis situated near the nails of the fingers. Under various forms they appear with this significance in the vernacular, and they are widespread in the dialects. From a philological point of view the most interest-

ing thing about them is the ingenuity which has been shown in devising spurious etymologies for them in order to explain their dialectal forms; to anyone not well versed in the philology which surround all such attempts they must seem not only plausible but practically convincing, thus yielding snap to the saying that obvious derivations are likely to be wrong ones.

J. W. L.

MOTOR CARS: THE SPARE PARTS PROBLEM

In regard to Dr. Garman's criticism (December 31st, 1906, p. 1121) of Mr. Massae Buist's article on the spare parts problem, published in our issue of December 17th, 1906, page 1045, Mr. Buist makes the following observations on Dr. Garman's seven heads:

1. The special urgency of the spare parts problem, as applied to members of the medical profession, was set out at length in the first paragraph of the article which is the basis of Dr. Garman's remarks.

2. Dr. Garman assumes that the spare parts problem concerns some members of the British motor industry only, and American manufacturers; whereas the article in question is treated in a number of ways how the spare parts problem exists also in connexion with the use of some foreign cars, including American varieties, though its cause is sometimes of a quite different character from that which governs the situation of a given British manufacturer. Let it, however, be made plain that the buying of a foreign car does not mean that the purchaser will not have difficulty in obtaining spare parts. These possibilities were set out at length in the article.

3. Dr. Garman here raises a question no less large than the proposition whether motor car development should have been arrested compulsorily in, say, 1906 and no progress made since evolution as from that date. His other statements here are highly controversial kind, but they do not concern the proposition in hand, since the article on which these remarks are based is not concerned with advancing the claims of one particular manufacturer against others. Further, it is sufficiently established that the world in general demands progress in motor vehicle design.

4. The statement that I have endeavoured to do my "best" to bolster up a rotten state of things, on which the whole significance of this paragraph of Dr. Garman's is based, is not true substance nor in fact, in that the tenor of my article was to illustrate, in the case alike of home and of foreign vehicles, the undesirable state of affairs, but the state of affairs that obtain owing to a variety of reasons set forth, this being a world in which man must necessarily live in a state of compromise. I am essentially a realist, and as such have to deal with facts, between which and wishes there is always a very clear and wide division.

5. Dr. Garman avers that I offered superfluous advice re making deposits to cover the costs of spare parts such as may be required and dilates about "such a ridiculous preceeding." He entirely misses the point, made abundantly plain in the article in question, that the suggestion was not mine; and that I deprecated such a course because a medical man had made that suggestion in a letter sent to your offices privately. It is therefore evident that such advice as I gave was needed, in that at least one medical man was entertaining the idea.

6. This paragraph, like all the preceding ones, is based on an assumption that I have striven to support a case for the British industry, and that all is well with the members of foreign industries. A re-reading of the article on which all these contentions are founded would prove that such assumptions are entirely false. The motorist experiencing difficulties in obtaining spare parts may be the owner of a foreign car, or of a British one; whereas Dr. Garman assumes that the British industry is the only one at fault. I know that, on the contrary, the spare parts problem obtains in the case of the world's motor vehicle products in general no matter of what country of origin. I therefore confined my attention to illustrating causes of unsatisfactory service to the medical men might be on the look-out for them and so safeguard themselves in ways indicated. But I regret I have no power to recast the actual conditions of motor trading the world over in this crisis in commercial history.

7. This is a continuation of the sixth point. The only further observation I have to make is that I cannot agree with anyone who advocates that if A is found to be at fault the owner of A should express his feelings in such a manner as to condemn all the letters in the alphabet. My theory is merely that when A is found to be at fault A should be specified in any condemnatory remarks; just as when Z is at fault the same should be done in respect of Z, instead of embracing the whole of the letters of the alphabet in the censure.

In conclusion, Mr. Buist writes, it would appear that I should make it plain that the various points touched upon in my article of December 17th are not of my raising, but have been brought to my notice by various medical men, for whose service I therefore set out the facts as they exist in the world of motor building and trading to-day, which is, as always, controlled by the bankers. Hence many desirable things are nevertheless impracticable because these businesses may be each a form of commercial enterprise. To deal with phases that are satisfactory was not my affair on the occasion in question.

WORK OF THE PENSIONS MINISTRY.

The fourth annual report of the Ministry of Pensions, which covers the period from April 1st, 1920, to March 31st, 1921, sets us a vivid picture of the human wreckage left by the war. At the end of the year the total number of awards of kinds in force amounted to 1,760,000, of which 1,200,000 in respect of disabled officers and men, and 560,000 in respect of widows and dependants. The total number of beneficiaries of all kinds was 3,365,000. Wounds and injuries accounted for about 42 per cent. of the total awards which have been made to officers and men, and 4 per cent. of the disablement awards were in respect of permanent disablement.

The total expenditure of the Ministry for the year was £105,660,000, as compared with £98,934,666 in the previous year. The average cost per occupied bed in the larger hospitals of the Ministry was 9s. 7d. per day.

FACILITIES FOR TREATMENT.

During the year under review 278,277 men were discharged from treatment, this figure not including those who had received home treatment; 148,818 remained under treatment at the end of the year. These were distributed as follows:

	In-patients.	Out-patients.
Orthopaedic	4,025	21,580
Paraplegic	260	231
Epileptic	597	541
Neurasthenic	2,951	6,975
Tuberculous	4,563	12,015
Rheumatic	1,015	2,897
Convalescent	1,018	
General, medical and surgical ...	8,747	38,601
Malaria	503	17,682
Dysentery	254	1,472
Other tropical diseases	45	703
Treatment and training	2,329	270
	26,342	106,005

In addition 16,471 men were receiving treatment at their homes and 6,271 pensioners classified as service patients were under treatment in mental hospitals.

Treatment has been provided partly by arrangements with civil hospitals and partly at clinics and hospitals under the direct control of the Ministry. In many cases the per capita fees paid to the civil hospitals have been increased. The following information is given with regard to certain classes of disability.

Special Surgical Cases.

At the end of the year 319 clinics had been opened for this type of case, 60 being under the direct control of the Ministry and the remainder under the administration of civil hospitals, the British Red Cross, or private individuals.

Neurasthenia.

There was an increased demand for treatment for neurasthenia, and eight additional hospitals, with a total accommodation of 1,356 beds, were established. One hospital with 185 beds was, however, closed. Forty-eight clinics for the treatment of neurasthenia had been opened at the end of the year. Much attention has been devoted to this disease. Its treatment presents many difficulties, not the least of which is the patient's liability to relapse during a period of economic or domestic stress. Full provision has been made for psychotherapeutic and other special forms of treatment, and successful results have been obtained by means of occupational treatment during a stay in hospital, particularly where it was possible for the patient to return to employment immediately on discharge. In connexion with this form of treatment, workshop officers were appointed to act in liaison between the medical staffs and employers of labour.

Tropical Diseases.

At the end of the year 61 clinics were in existence, 54 of which had been established by the Ministry. The

efficient treatment of tropical diseases has been found to depend upon expert clinical and pathological investigation in conjunction with the systematic recording of the history and progress of the case. In these respects there has been marked progress in the treatment of pensioners, and the type of disease has, in each case, been accurately classified. A large number of pensioners have been cured. The invasion of this country by tropical diseases has been stemmed, further dissemination has been obviated by preventive measures, and such special conditions as bilharziasis dealt with in the light of the latest expert knowledge. It is considered probable that in the future there will be a decline in the need for treatment of tropical disease, especially in the case of malaria.

Aural, Ophthalmic, and Cardiac Diseases.

During the year 36 aural clinics, 24 ophthalmic clinics, and 19 cardiac clinics were established, of which 16, 9, and 15 respectively were under the Ministry's control. Modern methods of diagnosis and treatment of cardiac diseases have been employed in the hospitals and clinics, and large numbers of pensioners suffering from functional disorders of the heart have been restored to working capacity.

Mental Diseases.

The care and treatment of the insane devolves upon the Board of Control, which is responsible to the Minister of Health. The Minister of Pensions is, however, intimately concerned with the care of certified pensioners, and an effective liaison has been established. Medical officers of the Ministry of Pensions with special experience of the treatment of mental diseases systematically visit mental hospitals and interview the pensioners under treatment. The close co-operation established has secured for the pensioner efficient treatment combined with the greatest degree of freedom and comfort compatible with the mental condition.

Tuberculosis.

The Ministry of Pensions co-operates with the Ministry of Health in the provision of adequate treatment for pensioners suffering from this disease. It has been decided that men who, on conclusion of treatment at a sanatorium, and who (when they are recommended to do so) undergo a prescribed course of treatment or training at a training colony, should be granted a pension at the rate of 100 per cent. for a period of six months after completion of such treatment or training, followed by a pension at the rate of not less than 50 per cent. for a further period of two years.

CONVALESCENT TREATMENT AND TRAINING CENTRES.

Seven of these centres, with a total accommodation of 2,382 beds, have been established. The training given at the centres is generally a preliminary part of the courses of training approved for men trained under the Ministries of Labour or Agriculture and Fisheries, although in some cases the course of training may be completed at the centre. In the case of "special" trades with which trade unions are specially concerned it is necessary to obtain the approval of the Trades Advisory Committees both as to the suitability of the trading arrangements and the individual fitness of the men to be trained. Notwithstanding difficulties and industrial depression, which affected employment in practically all trades, about 1,000 men had by the end of the year completed a course of concurrent treatment and training and were able to pass forward for the completion of training under ordinary conditions, or to take up employment.

MEDICAL BOARDS.

During the year 1,167,606 officers and men were examined, as compared with 1,038,905 examined during the preceding year. In addition, 4,393 examinations at discharge centres and 16,568 domiciliary examinations were necessary, since the pensioner's condition did not allow of his attendance before a board. The Medical Appeal Boards examined 71,332 officers and men. Thus during 1920-21 only 6 per cent. of the assessments of medical boards were challenged. Of the appeals 54 per cent. of the assessments were unaltered.

The report deals with various other matters not specially of medical interest. As a whole it demonstrates clearly that much energy and skill is being devoted by the Ministry of Pensions to the restoration to health of wounded and disabled officers and men, in so far as that is possible.

British Medical Journal.

SATURDAY, JANUARY 14th, 1922.

INFLUENZA.

SINCE the end of the third phase of the 1918-19 pandemic influenza has assumed threatening proportions twice. Early in 1920 outbreaks on a considerable scale began to occur in America, while the Ministry of Health gave warning of the existence of the disease in this country in the form of localized epidemics. In the great towns of England and Wales the numbers of deaths from influenza and of notified cases of pneumonia began to rise fairly steeply from the third week of the year and reached a maximum—392 deaths from influenza, 1,770 notifications of pneumonia—in the thirteenth week. The subsequent decline was, in the case of deaths from influenza, more gradual than the ascent, eleven weeks being required before the deaths fell to less than 100. In this recrudescence the proportion of deaths at ages 25 to 45 was 35 per cent., almost as many as in the first wave of the 1918-19 pandemic.

At the beginning of 1921 the deaths just exceeded a hundred a week, but then declined, and the vernal increase was comparatively trivial, the maximum at the beginning of March amounting to only 167. By the middle of May there were fewer than 100 deaths, and no significant movement took place until November. At the end of that month an increase began; 128 deaths were recorded in the week ending December 3rd, and the four following weeks have yielded 149, 212, 237, and 418 deaths. There has been a coincident increase of notified pneumonia, these five weeks having contributed 972, 1,013, 1,134, 1,157, and 1,235 cases. The proportions of influenza deaths in the age group 25 to 45 for the last two weeks of the year have been 21.5 per cent. and 25.6 per cent. In a comparison between the present position and that of the spring of 1920 the following features are to be noticed. The actual number of deaths attributed to influenza is already slightly larger than in the worst week of 1920 and the rate of increase is perceptibly faster. A qualification of this remark is perhaps needed, inasmuch as the statistics of the last week of the year may be disturbed by the holidays, but such disturbance was not noticeable in the influenza returns of 1920 and can hardly be of great importance. In predicting the immediate future, the sudden change of the weather last week must be taken into account, and, on the whole, it is probable that the first week of 1922 will provide a considerable increase of recorded deaths from influenza.

Are we, then, on the brink of another great epidemic? Against such an hypothesis are three statistical facts. The first is that the increase of notifications of pneumonia is much less pronounced than in the quite minor recrudescence of 1920. The second is that the proportion of deaths at ages 25 to 45, although increasing, is still much less than in 1920. The third is that in at least two of the northern manufacturing towns where influenza has been epidemic within the past two months the number of deaths have declined decisively. Clinical evidence in the same direction is that, in these cities, where special inquiries have been made, the pneumonia which was so terrible a complication of the pandemic has been a rare event and none of the so-called "heliotrope cyanosis" has been seen.

Again, if the statistics of the cities to which we referred above—Sheffield and Rotherham—be examined, it will be seen that the course of events has been quite similar to that of earlier and, relatively to 1918-19, mild outbreaks—namely, a rapid rise and fall, the complete sequence occupying only from four to six weeks. Always excepting the *annus mirabilis*, influenza of the past two generations has tended to become epidemic either at the end of the year or in the early spring. Looked at from the point of view of periodic recurrence—a subject which Dr. Brownlee has illuminated, and one which, as mentioned in the report of the Medical Research Council for 1920-21, is being subjected to experimental investigation—the present recrudescence is in season. It will be remembered that Dr. Brownlee concluded that the normal period was of approximately thirty-three weeks, autumn epidemics being aberrant. The last week of 1921 was the ninety-second from the maximum of the 1920 recrudescence; thirty-three weeks from the latter brings us into the autumn period, another thirty-three weeks into July, and a third period of thirty-three weeks takes us to the seventh week of this year. Allowing for fluctuations of a week or two either way, and for the probability that we have not yet reached a maximum, the concordance is fairly close.

These various pieces of evidence are consistent, and lead to the conclusion that the present outbreak is likely to resemble one of the minor recrudescences, such, for instance, as that of 1893-94, which was responsible for rather more than 2,000 deaths in London. This is, indeed, the conclusion which we think an epidemiologist would draw from the available data. But with the events of 1918-19 fresh in our memories, we should be foolish not to see elements of the problem which are disquieting.

Reference to the diagram prepared by Dr. Stevenson, and reproduced at p. 40 of the Ministry of Health's Report on the pandemic of 1918-19, shows that only in 1890 did the proportion of deaths in London borne by the age group 25 to 45 reach 30 per cent., and in no year later than 1901 but before 1918-19 did it attain 20 per cent. Examination of the weekly records since 1919 shows that, excepting odd weeks for which the returns were sparse, recovery to the pre-pandemic level has been incomplete. The age distribution of deaths is still quite different from that of the 1889-1917 period. Epidemic influenza has always been formidable on the rebound, and there is a possibility that correlated with the change of age incidence is an increased rapidity and force of rebound. If, to put the matter in the worst possible light, what is now happening is the analogue of the summer epidemic of 1918, the position might become very serious. As we have said, we do not think either the statistical or clinical facts make any such sequence probable, but they do not exclude it. The first evidence of any change of the sort would not be afforded by statistics of deaths but by clinical observation, and this is a time for the careful study of local variations in the type of disease and for rapid dissemination of knowledge.

We have no definite information with regard to the type prevalent at the present time. We have been unable to verify the stories which have been current about persons being taken ill so suddenly in the street as to be unable to get home: but undoubtedly in not a few cases the onset is very rapid. Instances of both the abdominal and of what is called the "cerebral" type have been observed, presenting symptoms which at the beginning have suggested appendicitis or meningitis respectively. Pneumonia, it would seem, has not become a very frequent occurrence. Last October Major Gatt, R.A.M.C., published in our columns a note on a series of cases, apparently influenza, accompanied by an erythematous eruption, which he had observed in the Curragh Camp; in some he had found Pfeiffer's bacillus in the throat in almost pure

culture; but we have not heard of any other cases in Ireland or elsewhere. It would be not only interesting but useful to ascertain whether the majority of the cases of influenza now occurring do belong to any particular type. We understand that the Ministry of Health is making inquiries, not yet complete, on this head, and would be glad to have information from practitioners who have encountered special clinical types. Such information should be addressed to the Medical Officer, Ministry of Health, Whitehall, S.W.1.

THE PROBLEM OF HOSPITAL FINANCE IN LONDON.

HOSPITAL finance in London as a whole is still in a very precarious position, and the temporary aid of the Government, welcome as it has been even in its modified form, has done little to stabilize matters. The cost of necessities may indeed have fallen a few points, but not to an extent appreciable in hospital balance sheets, and while trade remains bad voluntary contributions on the grand scale can hardly be hoped for, so that deficits on the year's working must inevitably be expected. The large provincial hospitals which to-day have least financial troubles are those which depend for the greater part of their income upon systematic contributions from the wage-earners.

In the report of Lord Cave's Committee the view was expressed that in the adoption of one or other of three schemes of mass contributions might be found the key to the financial problem which the voluntary hospitals have to solve. The first was a form of organized collection from wage-earners with no *quid pro quo*; the second, the Oxford scheme, under which a weekly contribution exempts the contributor from the patients' payments required from non-contributors; the third, the Sussex scheme, under which a larger weekly contribution entitles members to free consultation and treatment and to various other benefits inside and outside the hospital. Lord Cave's Committee pointed out that the Sussex scheme, as distinct from the others, implied a contract on the part of the hospitals to provide such institutional benefit as subscribers might require.

At a meeting held at the Mansion House last July representatives of the hospitals discussed these schemes, and requested the King's Hospital Fund to co-operate with the Hospital Saturday Fund, the London regional committee of the British Hospitals Association, and the other central agencies concerned in the organization of local collections from employees. A Joint Conference with these bodies was set up accordingly, and held a series of meetings at which the whole question was explored. Lord Cave's Committee had recommended a first grant of £1,000,000, to be followed, if necessary, by another, to give the hospitals two years' breathing space in which to work out schemes. Instead, the Government limited its grant to a maximum of £500,000, and attached a condition that before any grant (except a few emergency grants in exceptional cases) was made, fresh money had to be raised, or at least must be in sight, up to the combined amount of the emergency grants and of such further grant. Further investigations by the King's Fund had revealed that the estimated deficiencies in ordinary income of the London hospitals for the year 1921 would amount to at least £360,000, and that a number of hospitals had exhausted all their realizable assets and without immediate assistance would have no alternative but to close beds.

The position was placed before the Joint Conference and the London regional committee of the British Hospitals Association, with the result that the King's Fund was asked by the regional committee to prepare a

scheme for the organization of a general system of industrial contributions on provident lines. The King's Fund accordingly considered a provident scheme which had been drawn up by a subcommittee of the Joint Conference, and submitted it for the consideration of the London regional committee with an expression of approval of the general lines on which it had been drawn. The regional committee recommended it in principle to the constituent hospitals, which, it is understood, are now considering it. The scheme involves no contract for treatment, but the men and women of the hospital-using classes would be enabled under it to make provision by weekly contributions, and so to obtain exemption from patients' payments when undergoing ordinary hospital treatment, to which they would be admitted in accordance with ordinary hospital practice. In other words, the inquiry as to means which the almoner now makes at the hospital would take place when the contributor joined the scheme, and the hospitals would tell their prospective patients how much they should set aside, week by week, in order that, when admitted to hospital, they need not have to pay a comparatively large sum at a time when they can least afford it, or become a charge on charity intended for the necessitous. It is proposed that a weekly contribution of 3d. should entitle wife and dependent children to the same remission from patients' payments on admission to hospital, and it is hoped that collections will be made at the place of employment, by a request from employees to employer to deduct the contribution from wages, and that employers will contribute a portion of the weekly payment. Few large employers of labour—even those who consider themselves generous supporters of hospitals—have ever contributed sums which are really proportionate to the possible demands of their employees upon the hospitals. The employer of 100 workpeople, for instance, who sends a cheque for 10 guineas to the nearest hospital, hardly realizes that his contribution works out at less than one halfpenny a week for each employee.

The general aim of the scheme is to maintain the voluntary system intact, with its private administration of hospitals and its charitable treatment of the poor, by supplementing the present income of hospitals by the weekly contributions of regular wage-earners, who, by providing for the cost of their maintenance when admitted to hospital, will set free the gifts of charity for those for whom they were intended. It is hoped through the working of the provident scheme to decrease the pressure of minor cases upon the out-patient departments of hospitals by encouraging patients to consult their family doctor first and to come to the out-patient department when advised by him. If this can be effectually achieved the burden of the hospitals will be lightened, for there is no doubt that a considerable proportion of the patients who crowd into hospital out-patient departments could well be dealt with by their family doctors, and it is intended to bring the general practitioner into closer touch with the hospitals. The bounds of private practice would not be encroached upon, but the practitioner would be encouraged to procure freely for his patients, by recommendation and after consultation, those special facilities for diagnosis and treatment which are available only at the hospitals.

Such objections as have so far been made to the proposals outlined are regarded by the King's Fund as being based upon misconceptions and misapprehensions. It is held that the principle of the voluntary system is no more affected by such a provident scheme of weekly payments than it is by the system, now almost universally accepted, of asking patients while undergoing treatment to contribute to the funds of the hospital so far as their means allow; and from the

patient's point of view the former system is thought to be the less onerous. The object of the scheme is to preserve the voluntary system, to obviate bureaucratic control of hospitals, to systematize contributions, and to avoid that overlapping which in the past has been such a wasteful feature of the organization of hospital contributions in London.

THE UNIVERSITY GRANTS.

WE have received from Sir Michael Sadler, Vice-Chancellor of the University of Leeds, a copy of a memorandum which the heads of the sister universities of Birmingham, Durham, Leeds, Liverpool, Manchester, and Sheffield have addressed to the Prime Minister, urging on grounds of national importance the danger of any reduction in the grants now made by Government to the universities and university colleges of Great Britain. Since its dispatch to the Prime Minister, the Vice-Chancellors of the Universities of Oxford, Cambridge, London, Bristol, Wales, Glasgow, and Aberdeen have expressed their concurrence in it in a separate letter addressed to Mr. Lloyd George. The universities have received official information that it is proposed to reduce the grant, which for the year 1921-22 was £1,500,000, by the sum of £300,000. Such a reduction would gravely embarrass the universities in their work, especially in the development of advanced studies in science, medicine, literature, and technology; it will also inevitably restrict the work of the universities in adult education. The memorandum of the six Northern and Midland universities begins by expressing their obligation to the Government for the notable help given towards their support during recent years. It points out that these institutions provide opportunities of university education for 12,000 students, and that, recognizing the need for the utmost economy in public expenditure at the present time, the universities have restricted their outlay within the narrowest limits consistent with continued educational efficiency. To this end personal sacrifices are being made, and many developments, not only desirable in themselves but urgently needed, have been foregone. "But we are persuaded that the grants now made to us by Government are at the lowest level at which the due discharge of our duties to the nation can be guaranteed, and that any retrenchment would be hurtful to public interests and wasteful of outlay already made." With the aid of university grants these institutions were enabled during the war to render to the nation services of vital importance previously unforeseen; if the means are not withheld from them the British universities are in a position to give signal service to the nation during the coming years of peace. It is pointed out that the universities in England and Wales are now (as they have long been in Scotland) representative of the whole people. They are the recruiting and training ground for the great professions and for the public services, local and central; moreover, they train both workers and leaders for industry. The universities advance science, for they are the chief centres of research, and they extend the frontiers of knowledge in all other departments of study. Lastly, by means of student self-government and by the corporate life in residential halls, the universities train men and women for the responsibilities of citizenship. In short, the universities hold the keys of the future. But the funds which they now command are already inadequate. In order to meet their urgent needs every effort of self-help has been made: appeals have been launched, severe economy has been practised, fees have been raised, and the local authorities have nearly doubled their annual grants. "The Government urged us to make the efforts which have led to this measure of success by encouraging us to hope that what we raised locally would be met by a corresponding increase in Government grants." The memorandum then touches on the large measure of support given by the Governments of the United States, Canada, and Germany to their universities, and points out the importance they attach to them as centres

of training and research. In the United States gifts to universities, up to 15 per cent. of the donor's income, are by Federal Law exempt from Federal income tax. In Canada the universities receive increasing subsidies from public funds. The conclusion, therefore, is that retrenchment in the present grants would threaten the universities of Great Britain with debility and would check their growth. "Their work is part of the life insurance of the nation. To fail to keep up the premiums would, we submit, be unwise." We may express the hope that the Prime Minister, who recently made an eloquent appeal for the University of Wales, will give his sympathetic consideration to the reasoned and convincing appeal now addressed to him by the Northern and Midland universities, backed up as it is by the older universities in England and Scotland, as well as by the University of Wales itself.

LIST OF SCIENTIFIC PERIODICALS.

THE Conjoint Board of Scientific Societies (Burlington House, London, W.1) proposes to provide a world list of periodical publications which contain the results of original scientific research. It is hoped that it will be possible to give in a single octavo volume the titles, in alphabetical order, and the places of publication of all such periodicals in existence on January 1st, 1900, and of all issued after that date. The libraries in London, Oxford, Cambridge, Edinburgh, Dublin, and Aberystwith, which take in such periodicals, would be indicated, and, wherever possible, at least one library in the United Kingdom would be mentioned for each periodical. The scheme aims at supplying a complete list of current scientific periodicals; and, if means are found to carry it out, may form a basis of co-operation between libraries, so that both the number of duplicates and the list of periodicals not received may be reduced. The trustees of the British Museum have consented to allow the compilation of the list to be undertaken by the staff of the Museum, and already a large bulk of material has been collected in the Museum by various societies and by the Conjoint Board. The Museum, however, cannot undertake to defray the cost of printing and publication, but it is hoped that a sufficient number of libraries and institutions will agree in advance to purchase one or more copies at the price of 2 guineas each. The preliminary announcement which has been issued does not attempt to define a scientific periodical, but we apprehend that it is intended to exclude technical publications. It is not clear whether periodicals devoted to medicine would be included, and we understand that the point has not yet been decided. All departments of medicine, hygiene, and pathology, however, suffer more or less from the difficulty described, but it is felt to a very special degree by workers in these subjects in their application to the tropics; in particular the literature on helminthology, and indeed on parasitology generally, is very scattered, and papers which turn out to be of importance may be published in out-of-the-way periodicals, in the transactions of local societies, or in periodicals primarily devoted to some other science, as for instance entomology. Some time ago Professor R. T. Leiper, Director of the Department of Helminthology at the London School of Tropical Medicine, suggested that a list, showing the libraries in London and Liverpool at which periodicals publishing papers on tropical medicine could be consulted, would be of great use to workers, who at present may waste much time in making visits to libraries which do not contain the periodical they want or the particular number they wish to consult. The matter was brought to the notice of the Science Committee of the British Medical Association, which recognized the importance of the suggestion and in consequence a small sum of money was voted to cover preliminary expenses. A number of libraries have now been examined under Dr. Leiper's direction and a considerable amount of material collected, which it is hoped may shortly be made available. The manuscript list has been brought up to date and can now, we believe, be consulted at the School of Tropical Medicine.

SPIRITUAL HEALING.

THE Lambeth Conference in 1920 passed a resolution requesting the Archbishop of Canterbury to appoint a committee to consider and report upon the use with prayer of the laying-on of hands, of the unction of the sick, and other spiritual means of healing. It is contemplated that the findings of such a committee should serve for the general guidance of the Church in the matter of spiritual healing. We understand that a committee has been appointed, that its membership is drawn mainly from the clergy, but includes four or five well known members of the medical profession, and that the committee has already met on two or three occasions. The question of the formation of a ministry of healing was raised some years before the war by some enthusiastic clerics, and associations arose such as the Guild of Health in this country and Dr. McComb's church in Boston, U.S.A. Of the earnestness and sincerity of the founders of these associations there can be no doubt, though the movement may on the surface have seemed suggestive of an effort at a counterblast to "Christian Science." The success alleged in the cure of certain disorders through the agency of these and other forms of faith healing seemed to justify inquiry; and as long ago as 1909 the British Medical Association appointed a committee of investigation. Subsequently a mixed clerical and medical committee met, first under the chairmanship of Archdeacon Sinclair of St. Paul's, and later under Bishop Ryle, Dean of Westminster. This committee carried out a number of important and interesting investigations; but its labours were interrupted by the advent of the war. The committee which has been appointed by the Archbishop of Canterbury may have a somewhat different objective to that of Bishop Ryle's committee, and may be more concerned with the historical evidence for ministries of healing. Nevertheless it will not be able to avoid inquiry into the possibility of the use of what are called spiritual means in the cure of disease; of the methods which may justifiably be employed; and of the relationship of the clergyman and the doctor where such methods are used. Therefore we hope that the Archbishop's committee will make use of the material collected by Bishop Ryle's committee, if still available. Otherwise the paucity of members of the latter committee upon that which has been newly formed is hardly likely to lead to a speedy pronouncement upon a subject which is beset with many difficulties.

MOLIÈRE.

JEAN BAPTISTE POQUELIN, who when he became author and dramatist assumed the *nom de théâtre* "Molière," was born in Paris on January 15th, 1622—at least, his baptismal certificate bears that date. His father, who was upholsterer to Louis XIII, came of a prosperous bourgeois family of Beauvais, and there was once a tradition that some remote forbear was Scottish. Of medical practice in his day Molière was a bitter critic. He first satirized physicians in his farcical comedy *Le Médecin malgré lui*, and returned to the attack in *L'Amour Médecin*. His last comedy was *Le Malade Imaginaire*, in which he himself played the part of the sick man when it was produced for the first time on February 10th, 1673. During its preparation and rehearsal he had been suffering from cough and hæmoptysis, and before the third representation, on February 17th, he was so ill that he was advised not to act. He did act, however, but during the performance a violent paroxysm of coughing came on and he was carried away dying from the theatre to his house. Fielding's version of *Le Médecin malgré lui*, bearing the title of "The Mock Doctor," was first produced in 1732. In a later play, *M. de Pourceaugnac*, Molière giped at the physicians, and there can be little doubt that he suffered much at their hands during his long illness. The physicians and apothecaries of the day could not forgive Molière his bludgeon blows; but in exposing humbug and formalism he was a true friend of medicine, and

medicine will join with the other arts in celebrating the tercentenary of the great French dramatist. Paris this week is paying tribute to his genius. In London lectures on Molière's life, work, and times, are being given at the French Institute in Cromwell Gardens, and performances of his plays will be given on the afternoons of January 20th, February 3rd, and March 3rd; while on January 26th M. Antoine will come from Paris to London to lecture on Molière and his dramatic successors in France.

REPRESENTATION OF THE UNIVERSITY OF LONDON.

We announced a couple of months ago that Sir Philip Magnus, who has represented the University of London in the House of Commons since 1906, did not, owing to advancing years, intend to offer himself for re-election. For the vacancy which will thus be created at the general election it is probable that several candidates will come forward. Sir Sydney Russell-Wells, M.D., vice-chancellor of the university, has accepted the invitation of the Conservative Association to stand in the Conservative and Unionist interest. As the vice-chancellor is returning officer it will, we presume, be necessary for Sir Sydney Russell-Wells to resign his present office before becoming a candidate. It is probable that there will be a Liberal candidate, and we understand that the University Liberal Association has several names under consideration. It is stated that the Labour party will also put forward a candidate—probably Dr. Sophia Jevons.

VERNACULAR MEDICAL TERMS.

THE vernacular and the dialects of the British Isles are full of interesting words which have been used for centuries to express conditions of disease or of health, parts of the body and phases of the mind, and many other matters which are more or less medical in their meaning and relationships. Many of them are worthy of more attention than they commonly receive from the medical profession. Quite apart from their etymological, philological, and historical interest, they should have an attraction for the doctor because they are the words his patient often uses to describe his symptoms, to insinuate a causation, to express his fears, to voice an improvement, and, occasionally, to suggest a homely course of treatment. It is, for this reason, not below the medical man's dignity to endeavour to acquire some knowledge of the dialectal medical terms and phrases in common employment in the district in which his practice is situated, and to do so becomes almost a necessity if this district happen to be one far removed from where he himself was brought up. A wholly extra-academic and post-graduate course of language study is thus sometimes imposed upon the recently qualified man, not a little to his personal inconvenience until he is able to follow his patient in the details with which he or she is furnishing him in a hitherto unknown tongue; for he finds that his ignorance of the vernacular or the dialect places him at a disadvantage, his patient unfairly enough but with apparent logicity arguing that, if the doctor does not know so much as he (the patient) knows of the name of the disorder, the chances of his being capable of curing it will be small indeed. The doctor who, in certain parts of England, does not know that "the Yipers" there means chorea, or who, in Scotland, has not grasped the fact that "the rose" is a name for oryssiela, will find himself astray in his thinking and be caught considering snakes when he ought to be looking for muscular twitchings or meditating in a pergola when he should be looking at the skin at the sides of his patient's nose. But quite apart from this somewhat utilitarian reason for an insight into medicine in the vernacular and in the dialect there is the fact that now and again through the common word one can obtain a peep into the past history of medicine in this country, and can reconstruct in a measure old systems of treatment, refurnish the apothecary his shop with simples, and envisage the sick chamber or the lying-in room of the Middle Ages and the centuries immediately following them. For these and for such other reasons—etymological, lexicological, and philological—as may easily be imagined and will

in proper course appear, a beginning is made in this week's JOURNAL with the first of a series of articles on medical terms such as the common people use, and on the expressions and phrases, and even proverbs, in which these terms are embedded in daily speech. "Agnail" has been chosen for a subject on account of its curiously diverse forms, its changing meanings, and its strangely involved derivation; the facts have not been lost sight of that a hangnail (to give it one of its many other forms) on the finger of the best surgeon may embarrass his operation, and that its presence on the hand of a member of the staff of a venereal diseases department may introduce the danger of infection. Roger L'Estrange has put it on record that "the Ripping of a Hangnail is sufficient to Dispatch us." And this no doubt is literally true, and for no one more true than the surgeon.

GASEOUS DISTENSION OF THE SPLENIC FLEXURE.

ALTHOUGH Dr. A. F. Hurst¹ has pointed out that gas tends to accumulate more commonly in the splenic flexure than in any other part of the colon, and that patients mistaking it for gastric flatulence attempt to eructate the wind and thereby swallow air and so distend their stomachs, the subject has attracted very little attention in this country. It may therefore be worth while to refer to a recent study of this condition by Raymond and Berrien² of the Hôpital St. Antoine, Paris, illustrated by skiagrams. Their contention is that as the splenic flexure is the highest part of the colon gas tends to collect there, and that it may be derived from air swallowed and passed on; they found, indeed, that aerophagy and distension of the splenic flexure are often associated; this condition of the splenic flexure may be transient, but tends to become persistent. It may be independent of aerophagy and due to intestinal fermentation and putrefaction; or may be favored by idiopathic dilatation of the colon, by kinks, adhesions, the pressure of tumours from without, by paralysis of the left leaflet of the diaphragm due to pleurisy, and by atony caused by peritonitis. The distension of the splenic flexure may spread into the transverse colon as far as the middle line and to a more marked extent into the descending colon—namely, as far as the sigmoid flexure, but the distension always reaches its acme at the splenic flexure. The lower part of the left chest is asymmetrically prominent, tympanitic, and shows deficient respiratory movement and breath sounds. By skiagraphy it is seen that the left half of the diaphragm is displaced upwards for two or three finger-breadths by a clear, irregularly oval or circular area corresponding to the position of the splenic flexure; frequently the stomach is also distended with air, and then the two distended viscera can be distinguished. After a bismuth meal the splenic flexure shows a lining only along its inferior border, but a bismuth enema completely fills it up. In two cases the heart was completely displaced to the right. When the observer is on the look-out for the condition, the symptoms are highly suggestive; there is persistent feeling of distension, dyspnoea is caused by slight exertion, tachycardia and palpitation are constant, and constipation is the rule. The physical signs may even suggest a left-sided pneumothorax. Medical treatment consists in combating constipation, abdominal massage, and the use of electricity. When these measures fail entirely and the symptoms are severe, partial colectomy has been performed; in one instance the cure was brilliant, but in another cardiac failure caused death two days later.

ALKAPTONURIA.

ALKAPTONURIA is the term applied to the presence in the urine of homogentisic acid, a body by which Fehling's solution is reduced. Though a harmless condition it may when detected at a life insurance examination, cause rejection on the erroneous diagnosis of diabetes. It is a rare condition, but of great scientific interest, as it is one of the best known of what Sir Archibald Garrod has happily called "chemical malformations or inborn errors of metabolism." Other

members of this group are cystinuria, pentosuria, and albinism, in which the power of forming melanin is absent. Professor Campbell Howard and Dr. R. B. Gibson³ of Iowa, in reporting a new case with a study of its metabolism, point out that there are only about 70 published cases, 11 of these being American. Though familial it is not hereditary, and its incidence resembles that of albinism. There is a failure to complete the katabolism of the aromatic fractions of the protein tyrosine and phenylalanine, both from the food and the tissues, the process stopping at homogentisic acid, which is accordingly passed in the urine. In 1914 Gross found that the serum of normal animals and man destroys homogentisic acid, probably producing acetone, by means of an active enzyme which appears to be absent in alkaptourics. The urine when passed is natural in colour, but from oxidation rapidly darkens, especially when the reaction is alkaline; this, indeed, gave rise to the bilingual name alkaptone (from alkali and *κατὰ* = I gulp down), originally applied by Boedeker in 1861 to the reducing substance identified thirty years later by Wolkow and Bammann as homogentisic acid. Out of the 70 cases 24 (up to 1919) showed the inky black staining of the cartilages and fibrous tissues which Virchow called ochronosis; this may be attended by pain, swelling, and deformity of the joints. Ochronosis is not due solely to alkaptounria, but has been found to result from chronic absorption of carbolic acid. In 1912, in a note on ochronosis associated with carboloria, Drs. A. P. Beddard and Plumtre stated that out of 30 reported cases of ochronosis 14 were associated with alkaptounria and 9 with the use of carbolic acid, the chemical process by which this pigment is derived from these two acids being on the same lines. The appearance of patients with ochronosis is very remarkable, the pigmented cartilages, especially of the nose and ears, showing through the skin, which may also be black; the black pigmentation due to absorption of carbolic acid diminishes when the supply is cut off.

ASYLUM ADMINISTRATION.

THE Minister of Health has appointed a committee, consisting of Sir Cyril Cobb (chairman), Dr. R. Percy Smith, and Dr. Bedford Pierce, with Mr. P. Barter, of the Ministry of Health, as secretary, "to investigate and report on the charges made by Dr. Lomax in his book (*The Experiences of an Asylum Doctor*), and to make recommendations as to any medical or administrative improvements which may be necessary and practicable in respect of the matters referred to by Dr. Lomax without amendment of the existing lunacy laws." A review of this book appeared in our issue of August 20th, 1921, p. 288. The committee will ordinarily hear evidence in public, and the time and place of meetings for this purpose will be announced; the committee will, however, reserve the right to hear evidence in private in any case where they consider such a course desirable. It is particularly stated that the committee will hear such evidence as is necessary for the investigation specified in the terms of reference, but that it cannot undertake to hear evidence in regard to the amendment of the existing lunacy laws.

At the Church Congress at Birmingham in October last Lord Dawson of Penn made a speech, by invitation, on sexual relationships. It was reported in a condensed form in some of the newspapers, and has now been issued by Messrs. Nisbet as a pamphlet, for which Lord Dawson has written a foreword. Its price is 1s., and it can be obtained through any bookseller. We hope to refer to the pamphlet more at length on some future occasion.

PROFESSOR G. ELLIOT SMITH, F.R.S., will give a short address on the Rhodesian skull at the next social evening of the Royal Society of Medicine. The meeting will be held on January 25th; when Fellows and their friends will be received by the President and Lady Bland-Sutton at 8.30 p.m. The address will be given at 9 p.m.

THE WORK OF THE MEDICAL RESEARCH COUNCIL, 1920-21.

[FIRST NOTICE.]

THE Report of the Medical Research Council for 1920-21 may conveniently be regarded as consisting of two main parts: the one descriptive of the National Institute of Medical Research at Hampstead and the work done there, including investigations in experimental medicine and research work in certain clinical units which may be regarded as related to it; and the other giving an account of research schemes in specific subjects carried out at many different places. Of the fund at the disposal of the Council the larger part is expended under the second head, but the advantages of possessing a central institution have again been demonstrated. At Hampstead there are three experimental departments, but the work done in any one department frequently comes into contact with that being carried on in another, and one advantage of centralization is that the indications for future researches arising at these points of contact can at once be discussed between the workers in the several departments and general plans for further researches settled. The Institute also has the advantage of working in co-operation with the Lister Institute of Preventive Medicine.

As has been implied above, the work of the various departments overlaps here and there, but the following may be taken as a general indication of the matters which have chiefly interested each. The period under review, it should be noted, is the first full year of the Institute, which previously had been scattered in temporary quarters.

The Proteins of Bacilli.

An example of combined effort by two departments is afforded by a research conducted by Captain S. R. Douglas, Director of the Bacteriological Department, and Dr. Dudley, of the Department of Biochemistry and Pharmacology. Captain Douglas has continued his preparation of large quantities of the bacilli causing typhoid fever and tuberculosis respectively, for the purposes of an analysis of their proteins and other constituents; Dr. Dudley has continued his work on the intimate molecular structure of different proteins. For this purpose he has been able to use the bacteria, prepared in large quantities by Captain Douglas and carefully freed from their lipid constituents, for the preparation and estimation of the constituent amino-acids of the proteins, and for the application of Dakin's racemization method. This is work of a kind for which bacteriologists and pathologists have waited long, and it is satisfactory to know that good progress has been made in devising methods for the separation of the organisms in each case from the culture media.

Ventilation and Microbes.

Captain Douglas, working this time with Dr. Leonard Hill, Director of the Department of Applied Physiology, has continued investigations of the effects of ventilation and humidity on the air in a room or vessel massively infected by spraying with emulsions of micro-organisms. Humidity was found to make little difference to the rate at which the organisms settled out of the air, but it was ascertained that in a moist air the organisms condensed more rapidly on cold surfaces than on warm ones. It was ascertained, too, that dry air passed over organisms growing on the surface of an agar medium carried away many fewer than moist air; the presence of dust in the air also increased the number carried away. Efficient ventilation enormously increased the rapidity with which organisms were removed from the air of an infected room, and even keeping the air in motion with a fan had the same effect. Saturation of the air with moisture increased the results of movement.

Preservation of Antigen.

Researches commenced in 1916 into the antigenic properties of bacteria extracted with acetone and kept in a dry state have been resumed by Captain Douglas and Dr. A. Fleming; it appears that the antigenic properties of bacteria can, by this method, be retained indefinitely, and that bacteria so prepared are very suitable for the subsequent preparation of vaccines or for use in complement fixation tests.

Actinomycosis.

Further inquiries by Dr. Colebrook into the bacteriology of cases of human actinomycosis showed the value of adequate drainage, combined with vaccine therapy, in the treatment of the disease. Potassium iodide was not found to be effective. The need for the better differentiation of the diseases caused by actinomycosis and by allied organisms is noted.

Diphtheria.

With the assistance of Dr. R. A. O'Brien and his colleagues at the Wellcome Physiological Laboratories Dr. Colebrook has been able to follow the method of measuring the approximate strength of diphtheria antitoxin by means of skin reactions, and in this way has been aided in the study of the Schick test for the susceptibility of individuals to diphtheria, an account of which was given in our columns recently (December 10th, p. 994) founded on a report made to the Ministry of Health. It is hoped shortly to make a series of trials of the method, the underlying principle of which is the subcutaneous injection of a mixture of toxin and antitoxin.

Silica.

Dr. Gye, who has been working at tetanus serum with Dr. E. H. Kettle at St. Mary's Hospital, has investigated the nature of passive immunity against tetanus, with a view more particularly to finding how far the antiserum protects against infection with *B. tetani* as distinct from tetanus toxin. It was found that infection could not be produced by the injection of an ordinary culture of the bacillus, which is apparently unable to multiply in the normal tissues. To cause infection, with multiplication of the bacilli and development of the spores, the local defence of the tissues must be broken down by some such agents as ionizable calcium salts or colloidal silica. It was found that the prophylactic power of antitoxin serum, even in relatively enormous doses, was nullified or greatly impaired by the presence of calcium chloride or of silicic acid. It would appear, therefore, that active and passive immunity must be combined to give complete protection. Dr. Kettle and Dr. Gye have also investigated silicosis. It was known from the work of Haldane, Collis, and others that finely divided silica dust produced extensive fibrosis of the lungs; it has now been ascertained that hypodermic injection of both silicic acid and silica causes a lesion which ends in the production of fibroblasts. It is probable that the fibrosis of the lungs is caused by the silica in the tissues becoming hydrated and forming soluble colloidal silica which produces the damage culminating in fibrosis.

Protistology.

Much of the work done by Mr. Clifford Dobell, F.R.S., on the intestinal protozoa in man has been published in one of the Council's special reports and Mr. Dobell's book on the subject. Suffice it to say that there is now little doubt that about 50 per cent. of the population are infected with *Entamoeba coli*, which can gain admission to the human body only from faecal contamination of food; this indicates that in spite of the great modern improvement in sanitation there must be much negligence in the handling of foodstuffs. The need for greater care, both in commerce and in the household, is therefore urgent. It has also been ascertained that between 5 and 10 per cent. of people who have never been out of the country are infected with *Entamoeba histolytica*. This fact, taken with the known rarity of amoebic dysentery here, shows that over and above the infection with the amoeba some unknown causative factor is necessary before dysenteric symptoms can be produced in man.

Anaphylaxis.

Dr. Dale has had the assistance of Dr. C. H. Kellaway (Foulerton Student of the Royal Society) in resuming his study of anaphylaxis, interrupted during the war. Their results provide fresh evidence in favour of the view that the condition of anaphylaxis differs from that of immunity in the predominant location of an antibody in the body cells, immunity being due to excess of the same antibody in the blood cells and body fluids. Their experiments make untenable the view that "anaphylatoxin" is produced in anaphylactic shock, or that its formation has any direct bearing on the phenomena of true anaphylaxis.

Cinchona Derivatives: Digitalis.

A committee on cinchona derivatives and malaria has been appointed, with Dr. H. H. Dale as chairman, and Major H. W. Acton, I.M.S., Dr. Andrew Balfour, and Lieut.-Colonel S. P.

James, late I.M.S., as members. With the help of the Ministry of Pensions, arrangements have been made to distribute supplies of pure salts of quinine and quinidine for comparison of their effects in treating benign tertian malaria. Owing to the scarcity of cases progress is slow. Reference is made to the observations of Sir Thomas Lewis and his colleagues, reported in the *BRITISH MEDICAL JOURNAL* of October 1st, 1921, p. 514, on the power of quinidine to suppress auricular fibrillation in a certain proportion of cases; they were carried out in the Council's Department of Clinical Research, and the Cardiographic Department of University College Hospital Medical School, and form part of the researches directed to elucidate the nature of auricular flutter and auricular fibrillation. In the same department a series of experiments have been made upon the action of certain standard preparations of digitalis, with a view to determining the relative strengths of these preparations when used therapeutically. The preparations were supplied by the National Institute for Medical Research, and were part of the result of an inquiry by Dr. Burn into the methods of assaying digitalis. He found a wide discrepancy between those obtained by the different methods, the ratio of activity between two tinctures assayed by one method being inverted when the same tinctures were assayed by another.

Pituitary.

Dr. Dale and Dr. Burn have examined the methods advocated for the standardization of extracts of the posterior lobe of the pituitary body. Experience has so far shown that the sensitiveness of the plain muscle of the guinea pig's uterus to the pituitary extract on the one hand, and to the proposed stable standards (histamine or potassium chloride) on the other, varies independently. Attention is therefore being directed to obtaining a stable standard preparation of the pituitary active principles themselves.

Anaesthesia.

Dr. Leonard Hill and Dr. Dale have sought to obtain an improvement in the anaesthetic action of mixtures of nitrous oxide and oxygen, which is effected by giving the mixture from a flexible bag in a chamber under a small positive pressure. The possibility of producing deep and long continued anaesthesia in this way was demonstrated in 1878 by Paul Bert, but the occurrence of an accident, of which details are not available, appears to have prevented the adoption of this method for producing anaesthesia in man. Recent experience has made increasingly clear the harmlessness of nitrous oxide and oxygen, as compared with chloroform or ether, in cases in which toxæmia is present. Dr. Hill and Dr. Dale have revived Bert's observations, and, making use of the steel pressure-chamber at the Lister Institute, have shown the possibility of producing deep anaesthesia without cyanosis under conditions which, given a suitable pressure-chamber fitted as an operating theatre, could be applied to the human patient.

Kata-thermometer.

The investigations carried out by Dr. Hill, Director of the Department of Applied Physiology, and his colleagues, fall under two main headings—namely, practical questions of ventilation, and researches into the chemical changes of the body under various conditions of environment. The kata-thermometer devised some years ago by Dr. Hill, and described by him in our columns, has been used extensively in factories and mills by investigators of the Industrial Fatigue Board, by Dr. Chalmers, chief medical officer of health in Glasgow, for the estimation of ventilation in post office buildings, and by Dr. Orenstein and Mr. H. J. Ireland in South African mines. The important conclusion has been drawn that efficiency is lessened by as much as 50 per cent. when the kata-thermometer readings are lowest. Forminlac for use in interpreting the kata-thermometer readings have been worked out for varying rates of wind; the movements of air in all conditions of ventilation can now easily be ascertained, and it may soon be possible to establish standards of movements of air, cooling power, and evaporation, for mines, workshops, public conveyances, eating houses, and other crowded places. An electrically heated kata-thermometer has been devised, and a modification of the instrument can be used for regulating the temperature of a current of air.

Local Heating and Cooling.

Some curious results have been obtained from a study of the effects of local heating and cooling of the body, carried

out by Dr. Hill, Miss Ash, and Dr. Argyll Campbell. It appears that when the hands are placed as far as the wrists in water at 5–10° C. the whole body loses as much heat as is normally produced in the resting condition. Conversely, when the hands are immersed in water at, say, 44° C., the body gains almost as much heat as it loses normally. Since this indicates that local heating of the body may be very efficacious it is just possible that it may be found to be the best method of distributing heat in some workshops and elsewhere, each individual having an electrical heating appliance beneath his clothes and under his own control, while the whole shop is freely ventilated by cool air.

Oxygen Bed-tent.

Dr. Hill, with the help of Mr. R. H. Davis and Mr. Rosslyn, has constructed an oxygen bed-tent which encloses the upper part of the bed and allows the patient to breathe comfortably an atmosphere containing about 40 per cent. of oxygen. There is a fan for circulating the air and an absorber for the exhaled carbon dioxide. The tent has been used at the Duncane Hospital in collaboration with Mr. J. E. H. Roberts for the treatment of oedema and chronic ulcers following gunshot injury to the blood vessels of the leg, and at the Hampstead Infirmary for the treatment of chronic ulcers, with benefit in all cases. It is thought that the tent will be useful also in the treatment of pneumonia and surgical shock.

Statistics.

In the Department of Statistics, of which Dr. John Brownlee is director, Dr. Matthew Young, who has been investigating the geographical distribution of rheumatic fever, reports that there is a definite association between excessive prevalence of rheumatic fever and an excess in rainfall with a low mean annual temperature; the existence of this association has been denied. Dr. Young has also investigated the distribution of cancer in the Severn Valley; the results so far go to show that while there is considerable actual variation in the mortality in the several districts of the region there is no conclusive evidence in favour of the alleged association of an excessive death rate from cancer with low-lying areas or of a small mortality with high-lying areas and with the older geological formations. The inquiry seems also to indicate that the association between excessive incidence of cancer and pronounced industrialism is neither so direct nor so specific as has recently been asserted.

Research Work of Clinical Units.

Reference has already been made to the research work done at University College Hospital by Sir Thomas Lewis and his colleagues. Dr. J. W. McNece, assistant in the Medical Unit, has continued his experimental work on disorders of liver function. At the London Hospital two assistants of the Medical Unit have received grants. Dr. A. W. Ellison and Miss M. Leek have obtained evidence which confirms d'Herelle's theory as to the presence in the faeces of patients convalescent from dysentery of a filterable agent capable of destroying the dysentery bacillus of Shiga. A similar substance has been obtained from patients suffering from other conditions. It is found not to be specific; it destroys also *B. typhosus* and other organisms. At St. Thomas's Hospital Professor Hugh MacLennan, Director of the Medical Unit, has continued his investigations on nephritis. Part-time grants have been made to Dr. S. C. Dyke, pathologist to the Surgical Unit, and to Dr. P. C. Brett. Dr. Dyke has been seeking to correlate the microscopical changes found in diseased kidneys and the functional changes ascertained by biochemical means during life. Dr. Brett has done some research work on renal disease and on carbohydrate metabolism, but much of his time has been taken up in the examination by modern scientific methods, for the Ministry of Pensions in the London region, of more than 10,000 patients who were at one time the victims of trench nephritis. It is believed that if this investigation can be continued for a few years valuable results will be obtained.

Finance.

The grant in aid at the disposal of the Medical Research Council was nominally increased for the year 1920–21 by £5,000, making a total of £130,000. This increase was, however, coupled with the condition that no additional provision should be made by way of a supplementary grant or from the funds of any other department for the work of the Industrial Fatigue Research Board, and that the provision hitherto made for research work into mental disorders

under the direction of the Board of Control for England and Wales or the corresponding authority in Scotland should be discontinued and the work transferred to the Medical Research Council. The annual sum available in former years for mental disorders was £2,300. In the previous year the work of the Industrial Fatigue Research Board cost £18,000; towards this the Department of Industrial and Scientific Research made a grant of £8,000 and the Medical Research Council £10,000, of which £5,000 was from a special supplementary grant voted by Parliament. The Medical Research Council was thus called upon in the past financial year to meet additional claims under these heads amounting to £15,300, towards which it would receive £5,000. The administrative expenditure of the Council has never been permitted to exceed 6 per cent. of the annual expenditure; the expenditure of the National Institute for Medical Research at Hampstead had already been reduced, by economies and rearrangements, by some £4,000 a year. In the face of this position the Industrial Fatigue Research Board and the arrangements for its work have been remodelled, and many of the investigations already in hand and more in immediate prospect have been sacrificed. Every effort, however, will be made to maintain the continuity of the work of the Board, which has already earned the goodwill, both of the employer and employed, in many industries. It was not found possible to make any material reduction in the cost of the research work of the Board of Control, but some economies have been effected.

The volume and variety of the work supported by the Council has greatly increased since its beginning, and the increase in the grants received by the Council has borne no direct relation to the greatly advanced cost of each unit of work in an expanded programme. The remuneration of the workers has been increased, though to an inadequate extent, to meet the higher cost of living, and decreased as that has fallen. The rise in the cost of materials and apparatus has in most instances been of a far higher order than the rise in the price of food, and has not, it is stated, declined in anything like the same ratio. The total amount available, £130,000, was allocated as follows: To the National Institute for Medical Research, £38,000, to research in specific subjects (including mental disorders) at universities and other centres, to research in clinical medicine and to the Industrial Fatigue Research Board, £84,000, and to administration £8,000.

England and Wales.

TUBERCULOSIS IN WALES.

A CIRCULAR has been issued by the Welsh Board of Health to local authorities and medical officers of health in Wales with reference to certain details of the campaign for the prevention of tuberculosis. A form has been drawn up for the purpose of giving information as to persons who have been in contact with a patient suffering from tuberculosis, in order to ensure their systematic and prompt examination by the tuberculosis physicians; the form also provides for information as to the environmental conditions under which a patient is living. It is recommended that on the receipt of a notification that a person is suffering from tuberculosis the medical officer of health, or another officer of the local authority acting under his instructions, should visit the patient's home in co-operation with the medical practitioner in charge of the case. It is thought that the medical officer of health will be in a position to detect the possible source of infection and thus to lessen the likelihood of its continuance; he can also act with a view to the removal of any insanitary conditions tending to retard the patient's recovery. A leaflet of instructions to persons under treatment for tuberculosis has been prepared by the Welsh National Memorial Association, which is intended to be handed to patients attending at the tuberculosis dispensaries. The association will continue to supply free of charge to patients sputum flasks and bottles and the necessary means for rendering the sputum innocuous. The importance of the medical officer of health keeping the register of tuberculosis notifications up to date is emphasized, and local authorities are reminded that as tuberculosis is an endemic and infectious disease adequate cleansing and disinfection of rooms which have been occupied by patients, and of personal clothing, bedding, etc., should be carried out where the medical officer of health considers these measures to be desirable. Some local authorities appear to have failed to realize this obligation. It is advised that in Wales all

cases of persons suffering from tuberculosis should be brought to the notice of the Welsh National Memorial Association at the earliest possible date. In order to secure prompt notification it is suggested that local authorities should circularize the medical practitioners practising in their areas, drawing attention to the value attached to this and to the free utilization of the services of the tuberculosis physicians of the association, so that in any doubtful case a definite diagnosis may be arrived at as soon as possible.

LIVERPOOL MEDICAL INSTITUTION.

A meeting of the Liverpool Medical Institution was held on January 5th. with the President, Dr. J. E. Gemmell, in the chair. Mr. Edgar Stevenson read a note on extraction of cataract in the capsule of the eye lens, and showed lantern slides demonstrating Professor Barraquer's suction operation. Dr. Norman B. Capon read a paper upon intracranial traumata of the newborn. He had found intracranial haemorrhage in 21 per cent. of infants dying shortly after birth; ruptures of the dural septa, usually of the tentorium cerebelli, were present in 25 per cent. As might be expected, these figures were higher in cases of stillbirth; they were 46 and 60 per cent. respectively in his own series. After reviewing the etiology of intracranial injuries he discussed the difficulty of diagnosing the locality of the effused blood. In his own examples of infantile death following difficult labour slightly more than 50 per cent. revealed only a condition of cerebral congestion, for which early lumbar puncture was undoubtedly the appropriate treatment. Dr. A. Robertson Wilson read a paper on the treatment of surgical tuberculosis by sun-cure at Leysin. After a short account of the situation and climate of Leysin and the general arrangements of the clinics, he described the effect of the sun on the patients under treatment, making special reference to the relationship between browning of the skin and the progress of the case, and pointing out that the greater the pigmentation the better was the prospect of success; the relief of pain was also mentioned. He remarked on the excellent physical conditions of the patients he had seen, and especially on the development of muscles previously atrophied and the restoration of movement in affected joints. The treatment of Pott's disease and tuberculosis of the hip- and knee-joints, as carried out by Dr. Rollier, was described in detail, along with the methods for reduction of the deformity and the technique of the "sun bath." The striking successes obtained were illustrated by photographs lent by Dr. Rollier. The treatment of tuberculosis in other bones and joints, of adenitis, genito-urinary tuberculosis, and tuberculous peritonitis, was described, with the satisfactory results which followed. A short account was given of the treatment of convalescent cases and of the work colonies and open-air schools established by Dr. Rollier.

CORONERS' JURIES.

At the conclusion of four inquests concerning deaths due to violent causes, held on December 21st, 1921, Dr. F. J. Waldo, the City Coroner, informed the jury that unless Parliament intervened, the war measure known as the Juries Act, 1918, empowering coroners to hold inquests without a jury, would lapse on February 28th, 1922, and juries would then become necessary again in every case. At present the coroner was prohibited from exercising his discretion to sit without a jury in cases of (a) deaths in prison, (b) deaths requiring an inquest under an Act other than the Coroners Act, 1887—for example, the Lunacy Act, Children's Act, and the City of London Fire Inquests Act—and (c) where the coroner saw reason for summoning a jury, or for suspecting that the deceased had come to his death by murder or manslaughter (not including *felo-de-se*). The present practice of a large majority of coroners, both in London and elsewhere, was to sit without juries in some 92 per cent. of all public inquests; such cases included not only natural, but unnatural, violent deaths and suicides. A few coroners still sat in every case with a jury, while others—like himself—continued to summon juries save only in cases of sudden death in which the cause of death was unknown. These inquests usually resulted, after a *post-mortem* examination, in findings of natural death. Dr. Waldo added that in his courts the great majority of inquests (except those held in Holloway Prison) were upon cases of violent accidental deaths occurring in hospitals; in these the question of conduct and neglect—short of criminal neglect—often arose. In his experience facts, founded on evidence, could best be decided by a jury directed by the coroner, whose duty it was to explain matters connected with the law of the case under consideration. The want of uniformity

brought about by the present war practice of coroners might, to a large extent, be met and corrected by an amendment of the war Act permitting them to sit without a jury only in cases of sudden death in which the cause of death was unknown. Dr. Waldo thought that the confidence of the public would best be guaranteed by the retention of the jury at inquests in all cases at least of death due to violent causes. The presence of a jury added materially to the publicity of the proceedings, which seemed to him one of the most useful features of the coroner's court.

MANCHESTER ROYAL INFIRMARY WAR MEMORIAL.

A war memorial to former residents of Manchester Royal Infirmary has been presented by the medical board to the trustees of the infirmary, and is placed in the main entrance hall. It is a bronze tablet upon which are recorded the names of former house-physicians and house-surgeons who fell, and gives the dates of their resident service in the infirmary and the office they held there. The names are as follows: W. B. Pritchard, E. N. Cumliffe, D. Rodger, C. B. Marshall, W. A. Sneath, H. D. Willis, T. W. Martin, S. J. Linzell, G. Maule, K. Atkin.

Scotland.

EDINBURGH ROYAL INFIRMARY.

At the annual meeting of the Court of Contributors of the Edinburgh Royal Infirmary, Lord Provost Hutcheson, who presided, said that the report contained a number of very satisfactory features. When so many similar institutions throughout the country had had to curtail their activities through lack of funds it was a matter for thankfulness that the Edinburgh Royal Infirmary was enabled to continue fully its beneficent operations. The total ordinary income for the year amounted to £118,191, and it was very encouraging to note that in spite of the coal strike the contributions from the employees in the various coalfields had actually increased by £345, the total for the year being £9,660. The League of Subscribers continued to do excellent work, the amount received from that source being over £17,000, an increase of £4,385. The total income for the year had amounted to £133,000, but over £16,000 had been received as a special grant from the National Relief Fund. The excess of ordinary income over ordinary expenditure for the year amounted to £15,136. The sum to be administered under the Astley-Ainslie Trust for the relief of convalescent patients amounted to over £600,000, and substantial benefits would accrue to patients of the Infirmary during convalescence, but the fact must be emphasized that this Trust would give no relief whatever to the financial obligations of the Infirmary. In fact, these obligations would probably be increased, as the existence of the Trust would result in a larger number of acute cases being treated in the Infirmary.

Correspondence.

THE INCIDENCE OF VENEREAL DISEASE.

SIR,—In some of the letters which have recently appeared in the *British Medical Journal* on the subject of venereal diseases, statements have incidentally been made as to the prevalence of these diseases and the almost universal habit of promiscuous sexual relations among young adults. There are at the present people engaged in it

for the purpose of their propaganda, regularly exaggerate the incidence of venereal diseases and of immorality.

Several years ago an Austrian syphilologist stated that 95 per cent. of the male population had suffered from gonorrhoea at one time or another. This statement has appeared in various medical and lay books dealing with this subject, and, inferentially, has been applied to Great Britain.

It must be the common experience of all of us who have had charge of lock wards that our "prostitute" patients may be seen plying their calling on the streets in an infectious condition. It is well known to every general practitioner that there is a considerable amount of promiscuity among the young adult population. But while this is so, it is exceedingly ridiculous and most mischievous to exaggerate

the occurrence of immorality, as has been done recently. There are certain members of the general public who are only too anxious to have information from the medical profession which may help them to salve their own consciences.

There is, of course, no reliable information as to the prevalence of promiscuity, nor as to the prevalence of venereal diseases. I feel sure that every medical practitioner who has the experience derived from ordinary general practice will agree that the statements recently made are ridiculous.

Further, there is the evidence which can be adduced from illegitimacy statistics, from venereal diseases clinics, and other sources, that the vast majority of the population of this country are free from disease and live decently moral lives. It would in my judgement be a catastrophe if the young population of this country were to be brought up with the idea that everybody adopted some variety of promiscuity, and that therefore no great harm would arise if one lapse were committed.

From the point of view of the national health I am sure that every means should be taken to secure a high moral standard for every man and woman, and that adequate punishment should be meted out to those who depart from such a standard.—I am, etc.,

Birmingham, Jan. 31.

JOHN ROBERTSON.

TREATMENT OF CARCINOMA OF THE CERVIX.

SIR,—I have read with interest the letter on this subject by Dr. Herbert Spencer. He states "the object of this letter is to plead for the exercise of judgement in the operation to be performed"; and again, "our great need is to get the cases early, so that the dangerous operation, extended abdominal hysterectomy, may be avoided." No one will cavil at the necessity for the "exercise of judgement" or the "great need" "to get the cases early," but surely it is the employment of an extensive operation in the early cases which will yield the best results.

Clinical experience of cancer in all parts of the body serves to confirm the opinion that a thorough and complete operation in the early stages of the disease gives the sufferer the best chance of prolonged alleviation or permanent cure, and that the results so obtained are not equalled by any other method of treatment yet employed. Indeed the necessity for early and complete eradication is an important surgical principle to which cancer in the uterus should be no exception.

Now the mortality of the extended abdominal hysterectomy is high, roughly 20 per cent., and if continued will tend to discredit the operation, but it can be reduced by exhibiting surgical judgement in the selection of cases and by care in the technique of the operation. Any major operations if indiscriminately employed would soon be discredited both by the profession and the laity.

The test of a surgical operation as a therapeutic measure is the ultimate result obtained from that operation under the best possible conditions, and employed in the early stages of the disease for which it is performed. When this test is applied to the extended abdominal hysterectomy for early cases of cervix carcinoma I have no hesitation in stating that the results obtained are not equalled by any other method of treatment known to medical science.

I believe, when this operation is employed for the cases in which it is really suitable the mortality is well under 10 per cent. in expert hands; indeed, I have completed 100 cases with 6 deaths.

The estimation of an operability rate which was introduced from Germany is eminently fallacious, and to maintain it at a high level tends to encourage rash and hazardous operations attended by such a high mortality as to discredit surgery. It is easy to say, "So-and-So selects his cases," but to do an extensive operation without eradicating the disease only tends to stimulate the remaining growth, and should the sufferer survive her ultimate condition is worse. Moreover, palliative measures may make a patient comfortable for a considerable period.

The selection of cases suitable for operation requires the highest surgical judgement, and the greatest care should be taken in so doing, otherwise the surgical treatment of cervix carcinoma will be discredited. The dictum "if it is an easy operation it is a good operation" is as true for the extended abdominal hysterectomy as it was for vaginal hysterectomy in the old days.

Concerning the technique of the operation the prevention of infection from the cancer and the prevention of blood loss are two most important factors. My own technique is fully described in the *Transactions of the Obstetrical Society of Edinburgh*, 1911. Finally, I may mention that I have seen recurrence six, seven, and eight years after this operation.—I am, etc.,

London, W., Jan. 7th.

F. J. McCANN.

SIR,—British gynaecology is under such great obligation to Messrs. Comyns Berkeley and Bonney for the pioneer work they have done in this country for Wertheim's operation that I sincerely regret any suspicion of slight on their work through a little carelessness on my part. In preparing my lecture for publication I eliminated a mass of statistics, retaining Berkeley and Bonney's almost exclusively for this country, but unfortunately by an oversight retained their earlier statistics. I much regret this, though the difference is not nearly so great as would be imagined from Mr. Comyns Berkeley's letter. The figures I quoted were:

Mortality, 22.5 per cent.; operability, 67 per cent.; and cure, 26 per cent. for three years;

whereas their later figures in 1916 were:

Mortality, 20 per cent.; operability, 63.5 per cent.; and cure, 39 per cent. for five years.

The last shows a great improvement, and is the only error of any importance.

Dr. Speucer's plea for vaginal hysterectomy in early cases would have more weight with me if there was any certain method of diagnosing the extent of the growth prior to operation. In my experience abdominal section often reveals the growth to be much more extensive than I had estimated by vaginal examination even under the anaesthetic.—I am, etc.,

Manchester, Jan. 9th.

WM. FLETCHER SHAW.

"LOOSE CARTILAGE."

SIR,—In your issue of December 17th Mr. Pennell, under the above title, states that "the treatment is not easy, and the diagnosis is more difficult still," and that "cures are in the minority." I submit that this unsatisfactory state of affairs is largely due to incorrect diagnosis, but to some extent also, as Mr. Pennell states, to faulty technique in operating. Traumatic affections of the knee-joint are lumped under the blessed term "internal derangements of the knee-joint," and the inexperienced surgeon is apt to follow the line of least resistance and remove the internal or external semilunar cartilage as the supposed cause of the disability. I could recount many such cases, but one which has recently come under my notice will suffice to illustrate my point.

An undergraduate injured his knee at football on the last day of the Lent Term. According to his account, the knee swelled up, but he managed to "go down," and was incapacitated for the whole of the Easter vacation. On his return to Cambridge he came to me complaining that the knee frequently "gave way under him, and let him down." On examination I found that there was little or no fluid in the joint, which could be extended to the full. On putting tension on the lateral ligaments in turn, the internal ligament was taut, but the external ligament allowed of considerable separation of the tibia from the external condyle of the femur. There was no history of "locking" of the joint. I diagnosed a ruptured external lateral ligament, and prescribed a Marsh's splint with stops to prevent full extension of the joint, advising him to wear this apparatus for at least six months, gradually diminishing the angle of flexion.

I have previously treated many cases of torn ligaments on these lines with success. To my mind operative measures have little or no advantage, as after suturing the torn ligament the joint has still to be guarded from full extension for a similar period to allow of firm fibrous union of the ligament taking place.

During the Long Vacation he consulted a surgeon near his home, who, I presume, jumped at the diagnosis of loose internal semilunar cartilage, and advised and removed the supposed offender. The patient came to see me the beginning of this (Michaelmas) term. He informed me of the operation and complained that the knee still frequently gave way. He had, of course, discarded my splint. On examination I observed the operation scar over the inner aspect of the knee. On testing the ligaments as before I found that the external ligament was still loose, but the internal ligament was also

loose. Thus in the operation for the removal of an inoffensive internal semilunar cartilage the internal lateral ligament had been injured and the condition of the knee rendered worse than before. All I could advise was a continuance of the splint, strapped as before, to prevent extension of the knee for another six months.

It cannot be denied that there are many traumatic conditions of the knee which do not admit of accurate diagnosis as to the exact nature of the injury. But there are certain injuries of the joint which can be diagnosed with certainty, and, if correctly diagnosed, treated with every prospect of satisfactory results being obtained. Briefly, it may be stated that "locking of the joint" is pathognomonic of loose or torn semilunar cartilages, but, on the other hand, absence of a history of locking does not necessarily exclude this condition. In the absence of a history of locking and as a routine practice, the internal and external lateral ligaments should always be tested in turn and compared with the sound side. A torn ligament will be demonstrated by the fact that with the knee fully extended the tibia can be separated from the femur on tension being applied to the injured ligament, a movement which should not obtain if the ligament is taut and intact. These two injuries are produced in two totally different ways. The cartilage is slipped or torn by rotation of the tibia on the femur in a semiflexed position of the joint, whereas a lateral ligament is torn by a lateral bending force on the fully extended knee.

A more accurate knowledge of the anatomy and mechanism of the knee-joint, combined with a careful inquiry into the history of the accident and a methodical examination of the joint on the lines I have stated, would, I submit, considerably reduce the number of unsatisfactory results of operation on "loose cartilage."—I am, etc.,

Cambridge, Dec. 28th, 1921.

H. B. RODRICK.

TREATMENT OF GONORRHOEA BY ELECTROLYSIS.

SIR,—The pathology of organic stricture described by Mr. Wyndham Powell is indeed strange reading. He says the superficial layers of epithelium are necrosed and cast off. Because an open ulcer cannot often be seen he misses the fact that their loss is the primary event. The other happenings of cellular renewal, fibrosis and contracture, are really secondary. This disastrous loss of cells is due to localized chemical action, sometimes, perhaps, a bacterial toxin, but much more often due to a caustic. One has only to examine a few hundreds of the discharges from cases which have had those applications to find epithelial cells sometimes in groups to be the dominant cellular factor. These cells have been killed by the chemical applied, and there is a minority of leucocytes—that is, pus cells. This condition is the important feature of films from obstinate cases of gleet. This state is initiated by the irritant employed, and is one of the factors which make cases of gonorrhoea chronic.

The benefit which may be obtained by any such procedure is due to the resulting vascular engorgement of the region of the urethral membrane which has endured such a chemical assault. The flow of antibodies is increased with improved phagocytosis of the organisms at work. In my view the price—that is, the damage and necrosis to the part—is much too high for the benefit obtained by the method employed.

In a short account of such a group of cases it is impossible to include such a detail as dilatation or other accessory to treatment. Any cases that needed it were given dilatation, though most of the chronic cases had received all that ordinary methods could provide before I saw them. Although a good dilator is a useful instrument it nearly always makes a greater impression on the patient than on the bacteria.

With regard to rheumatism my facts can afford to stand.

Coming next to posterior urethral invasion Mr. Powell seems to forget the common way in which gonococci can reach the epididymis—namely, by the lymph stream. Quite often there is an epididymitis so early in the infection that the lymph highway must have been the path of arrival of the gonococci. Besides this there is the easy and fairly common happening of some tiny lesion of the membrane by a syringe or other object even at the meatus, with the same result.

Even excluding first attacks I am surprised at the rapidity of Mr. Powell's success in curing gonorrhoea by irrigation. Since the method is one I never use I can only realize the contrast of his claim with the time other workers usually claim in lectures or in published work.

I may perhaps remind Mr. Powell of a valuable paper on the routine treatment of gonorrhoea published during the war. The medical officers in charge of a large number of patients wondered whether the routine treatments were any real advantage. Half of the cases volunteered to assist a decision by having no treatment, the other half were treated. The result was that it was better for cases to have treatment, but it was, so to speak, no galloping victory for treatment. The scepticism of those colleagues of ours as to the results to be expected from ordinary treatments is a fair indicator of the truth. I must, however, correct one more error of Mr. Powell in the pathology of gonorrhoea. He speaks of the bactericidal power of flattened epithelial cells which replace those needed. Surely the polymuclear leucocyte is the only cell in which any such power has been proved. We also knew that this cell must be provided with the suitable opsonin. Have not so many of us insisted on the all importance of these leucocytes or pus cells, and that they and the valuable antibodies must be preserved and augmented by all possible means? I am tolerably sure that Mr. Powell has never seen the fixed epithelial cells of the part ingesting gonococci or any other bacteria. The poor fighting power of the thickened and whitened membrane which he describes is due to the thickening, to its relative anaemia, and consequently to the hindrance of access of the leucocytes and of the blood antibodies.

Mr. Powell has invented a good urethroscope and has much experience of venereal work clinically. I hope he will come to realize that my methods are based on what I hold to be the true pathology of the malady, and that they are essentially more conservative than the ordinary ones. I do not, of course, forget that all of us owe so much of our knowledge of phagocytosis and of Nature's conquest over infecting organisms to the fine work of Metchnikoff, Cohnheim, Waller, and of Wright and others, not forgetting Ledue, Lewis-Jones, and Sloan.

New ideas which lead to new methods in any sphere of work are of no use unless the immediate and ultimate results are really better.—I am, etc.,

London, W., Jan. 7th.

CHARLES REES, M.B., M.R.C.S.

SIR.—I see a statement by Mr. Powell in the JOURNAL of January 7th (p. 37), that he has treated a large number of cases of gonorrhoea without meeting with any arthritic complications. Might I mention that one of the worst cases of gonorrhoeal arthritis I have ever seen occurred after my having copiously irrigated the urethra of a patient who had only a forty-eight-hour-old discharge? I used weak permanganate solution. The unfortunate man was attacked within twenty-four hours with acute pain and swelling in his right knee-joint, the other joints in his arms and legs later becoming involved. He resisted all treatment, including vaccines, and has to-day a stiff knee- and ankle-joint. I note lately that at least one important venereal clinic still prescribes the old-fashioned bottles of medicine and lotion for injection.—I am, etc.,

Cleve, Jan. 7th.

HOWARD ENGLISH.

DIET AND DEVELOPMENT.

SIR.—In your issue of December 24th you publish a paper by Dr. Harriette Chick and Dr. Elsie Dallyell entitled "Observations on the influence of foods rich in accessory factors in stimulating development in backward children." In a footnote it is described as a report to the Accessory Food Factors Committee appointed jointly by the Lister Institute and the Medical Research Council. Under the circumstances I think it may well be asked how the authors have come to select so misleading a title. The action of the antiscorbutic factor is specific. It stimulates development only in those whose want of development is due to scurvy. It leaves untouched these, a hundred times more commonly met with, whose want of development is due to other causes. The authors recount the improvement which followed in the case of ten children when fruit juice was administered freely and continuously. Nine out of the ten had admittedly suffered from manifest scurvy.

I suggest that a more proper title for the communication would have been "Observations upon the influence of foods rich in accessory factors in stimulating development in children suffering from scurvy." The basis of the dietary received by these children before the fruit juice was given was cow's milk "at least three or four days old," which had been "heated at least once before delivery." At present the

criminate hopes and expectations have been aroused. A firm of manufacturers has actually placed upon the market a preparation which claims to possess the property of specifically stimulating the growth energy. There is great need to be careful. Fruit juice will not do anybody any harm. It will cure and it will prevent one thing only—scurvy. Just in the same way thyroid extract will cure one defect of body and of mind, and one only. Yet in practice we are apt to find that almost all mentally defective children, whether the backwardness is due to primary amentia, to birth injury, or to mongolism, have been embarked, with hopes that are sure to be disappointed, upon a course of thyroid therapy. If I were to write a paper recording the improvement of ten cretins upon thyroid extract, I should not call it observations upon the influence of thyroid extract in stimulating development in backward children.—I am, etc.,

London, W. Jan. 8th.

H. CHARLES CAMERON.

SUICIDE IN BORDERLAND CASES.

SIR.—A letter from Dr. Phillips appearing in the issue of the BRITISH MEDICAL JOURNAL for December 10th, 1921, quotes with approval the dictum of Professor G. Robertson of Morningside that "every case of melancholia is a potential suicide." One asylum in this country boasts the proud distinction of never having had a suicide for over thirty years—that is, that all patients who were in the least depressed were watched with such stern vigilance that not the slightest loophole for mischance was given. But so eminent an authority as Dr. Bedford Pierce has placed on record that he cannot regard this as a healthy sign.

What of the great majority of patients subjected unnecessarily to such a rigid regimen? The success of treatment is to be measured by recoveries, not by a drastic system of repression. The mistake lies in not recognizing the natural causes of depression. A mind harassed and worried by the slings and arrows of ill luck, a nature naturally buoyant worn out by long attendance upon others, a heart bereft of joy through sudden shock and loss—such things are happening constantly in the everyday life of mortals. Are the sufferers, in addition to their troubles, to be subjected to the seance of constant supervision and the ignominy of being "cabin'd, cribb'd, confin'd" by cast-iron regulations such as would crush the vitality out of anyone—not to speak of the danger with which such a situation is regarded by the outer world? A person who has once attempted in ever so foolish and fruitless a manner to put an end to himself is doomed to a fate more dreaded often than death. Many a one has been committed to an asylum on account of depression due to altogether natural causes; the depression is thereby intensified a hundredfold, and they are kept there because depression still continues. What proceeding could be more irrational? The real cure is to change the conditions. Once this is effected the desire to live will most likely reassert itself and life will again become worth living.

Nothing is more conducive to suicide than the dread of the asylum. No one ought to be subjected to the soul destroying vacancy and suppression which therein prevail except patients for whom such measures have become an absolute necessity. The very methods in vogue suggest to those imprisoned the frantic desire to snap the fetters at all costs, and get free. This is natural. Suicide is in most cases no proof of aberration (pace the far too frequently repeated verdict, "suicide while insane"). The legal standpoint from which such occurrences are viewed is gradually undergoing a change. It is coming to be recognized that suicide arises often from the clearness of vision which sees before it a vista of coming woe, which estimates in sharp outline the long dreary stretch of life ahead, bereft of strength or hope. Not infrequently the worst cases of suicide arise from the firm conviction in the unclouded mind that it would be better for others were the sufferer dead. In many countries suicide has been regarded as an heroic act. While a high death rate is looked upon without too much concern in our asylums, the dark hand of Fate is stretched relentlessly over the living.

The remedy for this misguided state of things requires no legislation. It does not lie in instituting antechambers or annexes to asylums, where the inmates are inducted under lunacy control, without any of the safeguards afforded by legal certification (as was proposed in the mental clause recently inserted in an ill-fated health bill, and still commended by the late Minister of Health).

This mental clause was a distinctly retrograde step. The antechambers were intended to become "feeders" to asylums.

whereas the real path of hope lies in the direction of emptying the asylums, and reducing the enormous sum of £6,000,000 a year spent in their upkeep. At a cost of one-sixtieth part of this huge expenditure the experiment might be tried of starting appropriate and cheerful sanatoriums or hostels for those whom there is no necessity to imprison. These could be run on a hospital footing, and apart from lunacy, so that no stigma or depressing atmosphere need attach to them. No legislative barrier stands in the way of the provision of hospitals free from detention for such as do not need to be certified. It would be a great boon to doctors to have places of this kind to which to recommend their patients in the earliest stages. Such a common-sense measure of expediency would prove itself in a short time and in very many cases a sure and certain preventive of insanity.—I am, etc.,

London, E., Jan. 7th.

S. E. WHITE, M.B., B.Sc.Lond.

HOSPITALS IN THE TERRITORIAL FORCE.

SIR,—As another late Captain R.A.M.C.(T.F.) *à la suite* from September, 1908, I am reading the correspondence in the JOURNAL on "Hospitals in the Territorial Force" with much interest.

From personal observation in three general hospitals at home and in four general hospitals and one special hospital in France, it seemed to me that those who had been keenest on their professional work at some time or another in their previous career—medical, surgical, or sanitary—made the best administrators, whether they were Regulars or otherwise. Though nominally attached to the home Territorial unit in this large town, where at one time during the war there were said to be more than sixty institutions of a medical kind for the sick and wounded, the difficulty I found was to get any local job at all, either general or special. Subsequently, when sent from France on sick leave, I applied on two occasions for local employment near my own home and practice, and was forthwith incontinently bundled off to another town about 100 miles away, on the home pay of a Territorial captain, R.A.M.C.

On the other hand, I never had any difficulty in getting to the more interesting life and unlimited opportunities for general and special work at the base overseas by volunteering direct to the War Office, with and without the permission of my O.C. for the time being. But, unless one is *persona grata* to the local administrative, much valuable time may be lost in getting overseas, while no work is guaranteed near one's home.

In this country it seemed to me ridiculous for part-time medical officers to go about in R.A.M.C. uniform. In London and Southampton many medical men attached to large hospitals had the good sense not to do so.

As regards decorations and promotion, I have no doubt we all get some of what we think we deserve; personally it is an abiding source of gratification to me that out of my twelve commanding officers I made no less than three "sit up." In other words, the distinction one just misses is most thought of; but consolation lies in having tried to do one's best.—I am, etc.,

WILLIAM COTTON, M.D., D.P.H.,

Bristol, Jan. 7th.

M.O., H.M.Prison, Bristol.

HOSPITAL POLICY.

SIR,—Dr. Hawthorne attempts, in his letter which appears in your issue of January 7th, with not a little literary persiflage, to castigate me for the definition of a voluntary hospital given in my letter appearing in your issue of December 24th, 1921. He more than hints that the definition is not one which I, as Chairman of the Hospitals Committee of the Association, am authorized to hold up for public instruction, but that it is my own personal view which I am attempting to foist on your readers under cover of a little brief authority.

True, the definition is my own in the sense that I agree with it; but it is the definition of the Representative Body of the Association. At the Newcastle meeting a special resolution was passed dealing with paragraph 50 of the Cave Report, and stating: "That this meeting disagrees with paragraph 50 of the Report of the Government Committee on Voluntary Hospitals, and maintains that the essence of the voluntary hospital system is the independent and voluntary management, and that this is in no way related to the conditions of service of the medical staff." (Minute 239.) Dr. Hawthorne's assumption of ignorance of the source of the definition is not without a touch of humour, for he himself was present when that resolution was passed. The report of the meeting shows that Dr. Hawthorne

made no protest, yet he could scarcely have been stricken with breathlessness at the novelty and audacity of that definition, for it was enunciated by inference at the Conference of Hospital Staffs held in December, 1920, which in the first resolution passed stressed "the voluntary method of administration of the voluntary hospitals" as the feature which "should be maintained." I can only think that at the moment when Resolution 239 was passed Dr. Hawthorne was suffering the shock of the loss, a few minutes earlier, of a wrecking amendment to the "Leicester" resolution, which amendment he had supported with an eloquence that was vastly relished, albeit it was wholly unavailing in its plea.

The second part of Dr. Hawthorne's letter is an exposition of his own views of what a definition of a voluntary hospital should be. He bases it upon a historical sketch, which I admit is accurate so far as the past, but cannot accept as true of the present. Instead of one single defining principle of the voluntary hospital Dr. Hawthorne prefers the support of three—"gratuitous management," "gratuitous professional services," and "gratuitous contributions." Since he demands so many as three legs for his support, I wonder he was not bold enough to require a fourth—gratuitous nursing—for surely a four-legged table is a rock of stability compared with a tripod. But consider his three. Since he does not discriminate between them we may take it that each is severally and jointly necessary to the existence of a voluntary hospital, and that the loss of one of them would mean the loss and extinction of the voluntary hospital. Such a position is demonstrably untrue. There are voluntary hospitals existing—nay, flourishing—to-day which were originally charities, but whose inmates are now paid for by statutory authorities. One leg of Dr. Hawthorne's tripod is lost, yet the institutions remain "voluntary," and are universally recognized as such. Possibly Dr. Hawthorne would claim that they live on in the odour of the sanctity of their past, or by reason of the sweetening influence of the inheritance of "gratuitous contributions."

When we come to the present I find that Dr. Hawthorne does not appear to have perceived the influence of changed economic and social conditions on the clientele of voluntary hospitals. Time was when all of these were the indigent poor. To-day we learn "that at no great hospital in the country is the proportion of inmates who could be called indigent poor higher than 20 per cent. The remainder are people able and in many cases willing to pay a part at least of their maintenance." Dr. Hawthorne will, I am sure, agree that these figures indicate a vast improvement in the condition of our people, and one in which all must rejoice. But it suggests, also, that the time may come when it will no longer be true that "the poor ye have always with you," so that according to Dr. Hawthorne's tripod definition the voluntary hospitals are doomed to die, and must give place to some unified system of State hospitals, very logical in their distribution, very complete in their equipment, and very thorough in their work, no doubt; but, alas! how lacking in freedom, elasticity, and in priceless human variation.

I have only one comment to make on Dr. Garratt's further letter. He is entitled to his view of the "Leicester" resolution and of the staff fund, and to further his view by every legitimate argument. But I maintain that his reiteration of the Cave Committee's "twenty-eight meetings," and the implication that paragraph 50 of the report is the quintessence of those twenty-eight meetings is a method of argument that does not do justice to either the Cave Committee or to Dr. Garratt himself.—I am, etc.,

London, W., Jan. 9th.

N. BISHOP HARMAN.

MULTIPLE TOOTH EXTRACTION.

SIR,—Mr. Montague Way is quite justified in his comments in your issue of December 17th last on multiple tooth extraction. In one respect the medical practitioner is not to blame, but his teachers are, who allow him to pass through a long training without being obliged to acquire an elementary knowledge of the most prevalent of all diseases and its conservative treatment.

In another respect, the advocacy of "have all your teeth extracted" may be attributed to the somewhat exaggerated views which are spreading both among the profession and the laity, as to the evils arising from diseases which affect the teeth. For instance, it is rarely necessary to remove all teeth when affected by pyorrhoea alveolaris; and any inflammatory

condition of the gums may be, and often is, mistaken for this somewhat intractable, but by no means incurable, disorder.

That greater care should be exercised by medical practitioners before pronouncing definite decisions is easily proved. I have under treatment a doctor who has taken a fortnight's holiday in order to have all his teeth out, as advised by two of his colleagues. Of course his mouth has been neglected because of arduous duties; but it was only necessary to remove two central incisors, as the cause of his ill health. He not only retains fourteen useful teeth, but he has escaped an amount of misery only known to those who have endured it.

There is an ethical side to this problem, which ought not to be lost sight of. The medical practitioner is in practice to save life, the specialist to save any part of life to which he devotes his attention. As mastication is one of the most important functions of the human body, no dental surgeon of experience will remove teeth unless he is convinced that by so doing he can improve the health of his patient.—I am, etc.,

R. DENISON PEBLEY,

Consulting Dental Surgeon to the
Chelsea Hospital.

London, S.W., Jan. 7th.

POST-GRADUATE COURSES IN VIENNA.

Sir,—With reference to the letter of Dr. R. P. Wenckebach on post-graduate courses of the medical faculty in Vienna, published in your issue of January 7th, the following facts, which I derived during six months' work in the oto-rhino-laryngological clinics of Vienna from May to November, 1921, may be of interest:

1. Private courses in any subject desired can easily be arranged. The fees generally are 4 dols. an hour, divided among those taking the course.

2. There are two rates of exchange for kronen—the external, quoted on the London Exchange; the internal, quoted on the Vienna Exchange. The internal is roughly 100 per cent. the more favourable to visitors.

3. Of the courses desired, 99 per cent. can be obtained in English, and knowledge of German is not essential, though desirable.

4. The amount of fees received is generally of greater concern than the signing of declarations disapproving of the exclusion of German-speaking doctors from international congresses and medical societies. I met no one who signed such declarations, neither was I asked to do so myself.

5. The American Medical Society was reorganized about June or July, 1921. One of their chief objects was to obtain the reduction of lecture fees. The net result was a general increase.

By no means all the American medical men visiting Vienna last year associated themselves with this society, nor should I recommend any Englishman to do so before acquiring knowledge of the personnel in control at that time.—I am, etc.,

Birmingham, Jan. 8th.

F. DOUGLAS MARSH, F.R.C.S.

BIRTH CONTROL.

Sir,—At the close of his valuable address on "Problems involved in the congress of the sexes in man," Professor Arthur Thomson refers to the use of artificial checks to prevent conception, and says: "As a rule, we cannot interfere with the normal courses of nature without some consequent evil result." Will he say, however, that the result (repression or promiscuity on the one hand, or excessive families on the other) of abstaining from artificial checks is not much more evil? The world's food supply is always increased so slowly that only a very small percentage of couples in the world can get sufficient food for more than three children.—I am, etc.,

B. DESLOR.

London, S.W., Jan. 9th.

CLAYDEN v. WOOD-HILL.

Sir,—I am sending you the fourth list of subscriptions to the Wood-Hill Fund, and should be much obliged if you would publish it in your next issue. The amount received up to date is just over £800.

I should like specially to direct attention to certain contributions from medical societies, medical staffs of hospitals, etc., which have greatly helped the fund, and which serve as examples of what might be done by similar bodies of practitioners in other localities.

	£	s.	d.
The Kent Branch of the British Medical Association	27	10	0
The staff of the Radcliffe Infirmary, Oxford	21	0	0
The Manchester Medical Committee	13	2	6
The Kesteven Division of the British Medical Association	5	5	0
The Medical Committee of the Durham County Hospital	5	5	0
The Medical Staff of the Macclesfield General Infirmary	5	5	0
Medical Staff of the Macclesfield General Infirmary	3	3	0
of St. Cross, Rugby	3	3	0

If each Division or Branch of the Association would take the matter into consideration, and send to the fund a

Divisional or Branch contribution appropriate to its membership, the total sum for which Dr. Wood-Hill has been made responsible as the result of the recent trial—£1,600—would soon be forthcoming.—I am, etc.,

HAMILTON A. BALLANCE,
Honorary Treasurer.

All Saints Green, Norwich,

Obituary.

THE LATE SIR G. S. WOODHEAD.

We are indebted to Sir James Mackenzie for the following tribute to Sir German Sims Woodhead:—

By the death of Sir G. Sims Woodhead there has passed away a most striking personality in the medical profession. Probably there was no one who had so many devoted and attached friends. He and I were students together and residents in the Edinburgh Infirmary in the years 1878-79, and since that time I have watched with great interest his distinguished career, and have felt it one of my greatest privileges to have been favoured with his friendship. I can only speak of a small portion of his work—indeed, I doubt if any individual is qualified to do more—for his interests were so varied and he threw himself into each project with all his heart. He never spared himself if he could help any deserving cause, and no one can estimate the influence his magnetic presence brought into the widely varied interests in which he participated.

I wonder if anyone has realized the work he has done in tuberculosis. He was early in the field, and others can better describe what he did in the laboratory and by experiment. We had occasion to consult him in connexion with our research work in St. Andrews, and we were not only greatly helped by his advice, but were astounded at the extent of his knowledge. He fully realized the chaotic state of the knowledge of tuberculosis, and recognized that some new conception must be introduced to guide further research, and he looked to the more accurate study of the clinical phenomena as the source of this new conception. But he not only realized this: he himself, though not a clinician, did more than anyone to make clinical observation more accurate and reliable. He recognized that one of the first events that happens to an individual who becomes infected by a microbe is a rise of temperature, and that the temperature varies with the infection. He reasoned that the invasion of the body by the tubercle bacillus would be accompanied by a temperature

peculiar to the infection. The methods in use were totally unsuited to the purpose, and he sought for some other methods. The late Professor Gamgee had devised a method for taking a continuous record of the temperature, but had not quite perfected his instrument when he died. Woodhead adopted Gamgee's method, completed the details, and set about a long series of observations, which resulted in demonstrating the peculiar temperature curve which is caused by an active tuberculous process. The importance of this work of Woodhead's has not been recognized and its significance has not been understood. Apart from its value in recognizing an early stage of tuberculosis, it is the only important advance that has been made in clinical thermometry for over fifty years.

His continued interest in tuberculosis is seen in the establishment of the Papworth Colony for Tuberculosis, for which he was largely responsible. It may be too soon to speak of the success of this undertaking, but no system for the treatment of tuberculosis has been started by one with such a profound knowledge of the disease, and with such a common-sense appreciation of its aims and objects. Into this matter he threw himself with all his energy, though severely crippled by ill health.

There never was a man in our profession more desirous of helping anyone who was anxious to do good work; no one in need ever called on Woodhead in vain if it were in his power to help. Many members of our profession owe him a great debt. He took no credit to himself for anything he did; he was modest even to self-effacement, so that few knew what he had done, either in his own work or in the help he gave to others. I have a vivid recollection of the support he gave me at a time when I needed it sorely. About thirty years ago he mentioned to me that he was starting the *Journal of Pathology*. I told him I had been working for some time getting records of the venous pulse studying them to find out the mechanism of the irregularity, but a paper I had written had been refused by two or three medical journals. He at once offered to publish the paper in the first number of his journal. This was done, and a few days after the journal appeared he was accosted by a distinguished professor of one of the English universities, who asked him what he meant by publishing "stuff" from a fellow called Mackenzie, who was only a general practitioner and had no laboratory training. Woodhead replied that he did not know anything about the "stuff," but he was prepared to publish anything Mackenzie would write. His wife used to say of his friends that to Woodhead all his guests were wans, and I am not sure that his having a high opinion of his friends did not stimulate his friends to be worthy of his high opinion. At all events, when he told me of the above incident I felt determined to do my best to merit his opinion of me. I mention this incident merely to illustrate the kind of influence he exerted, and to those he helped he was ever encouraging, yet critical; and this encouragement and criticism, and his store of knowledge, were always at their service.

Then the large-heartedness of the man, his wonderful charity! He was ever seeking for the good that was in a man. His trust in human nature was extraordinary. How many people he helped financially it is impossible to tell. Of course his generous nature was taken advantage of, and to the end of his life it was the easiest matter to get money out of him with a tale of woe. Indeed, so often was he preyed upon that I had to ask him as a matter of course, "who has been 'doing' you last." Then with a laugh he would tell me the specious story by which some rascal had "borrowed" money of him, but never with any bitterness, and always with an expression of pity for the poor devil who was driven to such a strait. Some people might think it was because he was simple—and he was simple in a large way—but his being imposed upon was not due to simplicity, but entirely to his faith and the fundamental goodness of his nature, and though well aware he was being deceived, he knew that many whom he had helped were both deserving and grateful. No one will ever find out who he helped and how he helped them.

Then the courage of the man! For some years he had a perfect knowledge of the deadly nature of his complaint. Time and again death had stared him in the face, but as soon as he recovered, though well aware that his life hung on a thread he resumed his work with unabated energy. He knew that if he took things quietly he would live for years, but he preferred a period of work, however short, to living a few more years in idleness. A few weeks ago he had come north on one of his whirlwind expeditions to visit various tuberculosis institutions in order to find the best means to help his stricken fellow creatures, for whom he had instituted the Papworth Colony. Though manifestly feeble he was bright and cheerful, making light of his infirmities, even jesting at them and determined to die as he had lived.

These words give but an imperfect picture of a great personality.

Dr. C. E. DOUGLAS (Cupar, Fife) writes:

The death of Sir German Sims Woodhead brings to many outside his immediate circles a sense of personal loss. It takes the present writer back to those days, away in the middle seventies, when we were both active members of the Edinburgh University Athletic Club. For Woodhead was not only a keen and earnest student; he was a brilliant Rugby half, and the most graceful sprinter of his time, a many-sided youth, full of ideas. Politics were a joy to him, and his ardent mind was full of schemes and of hopes. A total abstainer even then, he would have all men be as himself. Of purely English blood he had, one would have said, the *perseveridum ingenium Scotorum*, and all through his life was dominated by the desire to be doing in the service of man. When the war came he flung himself into action, and it is probable that the overwork which he underwent brought on the disorder which eventually proved fatal. But even after the war, handicapped as he was by illness, he had yet time to do something more for his fellow men. In the summer of 1919, not long before the Cambridge meeting, he was in St. Andrews, fully alive to the important step that was being made by Sir James Mackenzie, and actually going about to beat up supporters for the Clinical Institute scheme. And it must be only a few weeks since the writer saw him, alas! for the last time, on his way back from St. Andrews where he had been making another visit to this the last great movement with which he was to be connected. It is over now, the day's work for him is done; but his old friends will not forget his ardent spirit, his keen sagacity, his ever ready, kindly smile. *Adieu atque vale.*

Dr. WILLIAM RATTRAY PIRIE, O.B.E., died at Aberdeen after a long illness, on January 5th, at the comparatively early age of 53. He was educated at Aberdeen University, where he graduated M.A. in 1888 and M.B. C.M. (with distinction) in 1892. He subsequently studied at Leipzig and Vienna, and was appointed assistant to the professor of medicine at Aberdeen in 1894. He became assistant physician to Aberdeen Royal Infirmary, and later honorary physician and lecturer on clinical medicine. He was also physician to the Institute for the Deaf and Dumb, Aberdeen, and was a certifying factory surgeon. During the war he was attached to the 1st Scottish General Hospital with the rank of Major, R.A.M.C.(T.), and he was afterwards a member of the Pensions Board. In recognition of his work during the war he received the O.B.E. He is survived by his widow and one son.

The Services.

DEATHS IN THE SERVICES.

Colonel John Thomas Brownrigg Bookey, C.B., Bengal Medical Service (retired), who died at Bournemouth on November 19th, 1921, aged 74, had probably taken part in more Indian Frontier wars than any other officer of his day. He was born at Carnew, Wicklow, and was educated at Trinity College, Dublin; he took the L.R.C.P. (Edin.) and the L.R.C.S.I. in 1871, and entered the I.M.S. on March 30th, 1872. He attained the rank of colonel on May 2nd, 1900, and retired on June 16th, 1905. For twenty-seven years (1873 to 1900) he served in the Panjab Frontier Force. He had a long list of war service, having served in no less than eight campaigns on the Indian Frontier, besides the China war, as follows: Jowaki campaign, 1877-78, medal; Mahsud-Waziri, 1881; Burma, 1886-87, operations of 2nd and 5th Brigades, and Wuntho expedition, mentioned in dispatches, two clasps; Hazara, 1888, dispatches, clasp; second Miranzai, 1891, dispatches, clasp; Waziristan, 1894-95, dispatches, clasp; Malakand, 1897, dispatches, medal; China, 1900, dispatches, medal with clasp, and C.B.; Waziristan, 1902, dispatches, clasp. He received the C.B. on November 29th, 1900, for the China war, and a good service pension on June 16th, 1902.

Lieut.-Colonel Bernard Doyle, Bengal Medical Service (retired), died in London on November 28th, aged 71. He was born at Ennisclorthy on September 16th, 1850, and educated at Trinity College, Dublin, where he graduated M.B. and B.Ch. in 1875. Entering the I.M.S. as surgeon on March 31st, 1876, he became surgeon lieutenant-colonel after twenty years' service, and retired on July 30th, 1902. After five years spent in military employment, during which he served in the Afghan war of 1878-80, and received the medal, he took civil employment in the Panjab, where he served as Deputy Sanitary Commissioner, as medical officer of Jhind State, and as civil surgeon successively of Ambala, Delhi, Firuzpur, and Peshawar.

Lieut.-Colonel Joseph O'Brien, Bengal Medical Service (ret.), died at Dewstead, Instow, Devon, on December 29th, 1921, aged 77. He was born on January 8th, 1844, the elder son of Michael Joseph O'Brien, of Dungannon, Waterford, and educated at Queen's College, Cork, and at the Ledwith School, Dublin. He graduated M.A. in 1869 and M.D. in 1870 at the Queen's University, Ireland; he took also the M.R.C.S. in 1869 and the L.R.C.P. and S. (Edin.) in 1870. He entered the I.M.S. on April 1st, 1870, became brigade-

surgeon-lieutenant-colonel in 1895, and retired with an extra compensation pension on August 19th, 1898. His first ten years' service were spent in military employment in the Assam Light Infantry, and during this time he served on the Nurtle-Past Frontier, in the Naga Hills campaign of 1879-80, when he was present in the action at Korumal, was specially mentioned in dispatches in 1880, and received the traunter medal with a clasp. In May, 1881, he went into civil employ in Bengal, where he served as civil surgeon of Arrah, Badwan, and Darjling successively. In April, 1892, he was appointed Professor of Anatomy in the Medical College, Calcutta, and second surgeon to the College Hospital, appointments in which he had previously acted in 1884-5; he held these posts till his retirement. The late Colonel Bartholomew O'Brien, F.R.C.S., was his younger brother.

Major Laurence Campbell Vigor Hardwicke, R.A.M.C.(F.), died in the Military Hospital at Haifa, Palestine, on December 10th. He was the younger son of the late Mr. John Hardwicke of Portland, Somerset, and was educated at Edinburgh, where he graduated M.B. and Ch.B. in 1904, and took the special certificate for tropical diseases. After filling the post of resident medical officer of Paddington Infirmary he entered the Egyptian Medical Service, where he served as medical officer of the Assuan reservoir district, with medical charge of the hospital and engineering works of the Assuan dam. He took a commission as lieutenant, R.A.M.C.(F.), and medical officer of the 1st Battalion of the City of London Regiment, the Territorial Battalion of the Royal Fusiliers, on July 22nd, 1905, becoming captain on January 22nd, 1909, and major on July 25th, 1917; he served as such throughout the war.

Surg.-Commander Thomas Francis O'Keefe, R.N. (retired), died at Richmond on December 23rd, aged 47. He graduated M.B., B.Ch., and B.A.O. in the Royal University, Ireland, in 1893, after which he entered the navy, attaining the rank of surgeon commander on February 1st, 1915, and retiring in 1920.

Medical News.

THE Home Secretary has appointed Lieut.-Colonel P. S. Lelean, C.B., C.M.G. (formerly of the Royal Army Medical College), to be an inspector under the Cruelty to Animals Act, 1876, which relates to experiments on living animals.

IN view of the importance of the early diagnosis of small-pox the London County Council has issued to medical practitioners in the metropolis a circular regarding the arrangements under which in doubtful cases the certifying practitioner confers with the medical officer of health of the borough. Should a further opinion be required, on application to the Public Health Department of the Council, 2, Savoy Hill, W.C.2 (Tel. No. Gerrard 3641), the services of Dr. Wanklyn will be available at any time of the day or night and during week-ends.

A COURSE of twelve lectures on the management and feeding of infants and young children will be given to medical practitioners by Dr. Eric Pritchard at the St. Marylebone General Dispensary, Welbeck Street, W., on Wednesdays and Fridays at 6 p.m., commencing on February 3th. Practitioners attending the course will be entitled to attend the infant consultations at the Dispensary on Tuesdays and Thursdays at 11 a.m. and 3 p.m. respectively, when demonstrations will be given. Opportunities will also be afforded of visiting on Saturday afternoons the Nursing Training School at Golders Green.

THE annual dinner of past and present students of the Royal London Ophthalmic Hospital (Moorfields) will be held at the Langham Hotel, on Thursday, February 9th, at 7 for 7.30 p.m., under the presidency of Dr. James Taylor, consulting physician. The price of tickets (excluding wine) is 15s.; application should be made to Sir William Lister, 24, Devonshire Place, W.1.

AT a meeting of the Medico-Legal Society, to be held at 11, Chandos Street, W.1, on Tuesday, January 17th, at 8.30 p.m., Professor Harvey Littlejohn will read a paper on "The proof of live birth in criminal cases."

AT the National Colonial Exhibition at Marseilles this year a congress of public health will take place, from September 11th to 17th, under the presidency of Dr. Paul Gonzi, President of the Superior Council of Health for the French Colonies. Further information may be obtained from the Central Organizing Committee, 55, Rue Paradis, Marseilles.

Dr. LOUIS CASSIDY, F.R.C.S.I., has been elected Master of the Coombe Lying-in Hospital, Dublin, in succession to Dr. MacLavery, whose period of office has expired.

THE period for which Mr. G. B. Mower White, F.R.C.S., was appointed honorary surgeon to the Royal Northern Hospital (formerly the Great Northern Central Hospital) having expired, he has been appointed emeritus surgeon in order that his services may be retained.

SIR ARTHUR KIRTH will give six Hunterian lectures in the theatre of the Royal College of Surgeons, Lincoln's Inn Fields, on the facial characteristics of living races of mankind, illustrated by specimens from the collection of human osteology in the museum of the College. The first lecture, to be delivered on Monday, January 16th, will deal with the facial characters of the Australian aborigines and allied native people; the second, on January 18th, with the negro and negroid types of face and skull; the third, on Friday, January 20th, with the Mongolian face and its modifications; the fourth, on January 23rd, with the European face and its chief variations in type; the fifth, on January 25th, with the study of certain aberrant types—bushmen, Eskimo, Lapp, and Ainu; and the sixth, on January 27th, with the facial characteristics of the races native to India. The lectures will be given on each day at 5 p.m.

THE number of deaths from influenza in the week ending January 7th is stated provisionally as follows: For the great towns, 795; for London, 352 (151 in the previous week).

POST-GRADUATE courses will be given during the next three months at the National Hospital for the Paralyzed and Epileptic, Queen Square, W.C.1, as follows: (1) A course of clinical lectures and demonstrations; (2) a course of neuro-pathology; (3) a course of six lectures and demonstrations in neurological ophthalmology. The complete syllabus and information regarding fees may be obtained from the Dean of the Medical School, Dr. C. M. Hinds Howell. Courses (1) and (2) will begin on Monday, January 16th, and Course (3) on Wednesday, February 1st.

DR. IAN MACDONALD of Huelva and Seville, Spain, has been elected a corresponding member of the Society of Surgeons of Paris.

MUCH interest is being shown by the American medical profession in a series of questions put by the *Journal of the American Medical Association* to over 54,000 practitioners in the United States on the uses of alcohol; over 30,000 answers have already been received and are being examined. The purpose of our contemporary is to obtain an authoritative expression of opinion from the medical profession on alcohol as a therapeutic agent. The inquiries have been sent to every other practitioner whose name appears on the mailing list of that journal, and to some 10,000 other practitioners throughout the country. The questions relate to the type of practice in which the practitioner is engaged; whether he regards spirits, beer, and wine as necessary therapeutic agents in the practice of medicine; whether in his experience unnecessary suffering or death has resulted from prohibition; how often he has found it necessary to prescribe these liquors; and whether he considers restrictions should be imposed upon members of the medical profession in prescribing them. The answers will be tabulated.

A MONUMENT to J. B. A. Chauveau, formerly president of the Académie des Sciences and of the Académie de Médecine and professor at the Natural History Museum at Paris, is to be erected at the Veterinary School at Lyons, where his principal discoveries were made.

ACCORDING to the *Wiener klinische Wochenschrift* the medical profession in Brazil have collected the equivalent of 150 to 160 million kronen to relieve distress among the medical profession in Austria and Germany.

THE late Mr. William Henry Clarke, of Southwick Crescent, Hyde Park, who died in October, 1921, leaving £70,124, has bequeathed £500 each to the London Hospital, Middlesex Hospital, St. Mary's Hospital, West London Hospital, St. Thomas's Hospital, Guy's Hospital, University College Hospital, and King's College Hospital; £300 each to the Cancer Hospital, Fulham Road, East London Hospital for Children, the Florence Nightingale Hospital, the Chelsea Hospital for Women, and St. Bartholomew's Hospital; £250 to the London Fever Hospital; £100 each to the Metropolitan Hospital, Kensington Dispensary and Children's Hospital, and the Poplar Hospital; £100 each to the Royal Dental Hospital, Leicester Square, the Paddington Dispensary for the Prevention of Consumption, Queen Charlotte's Lying-in Hospital, Royal London Ophthalmic Hospital, St. George's Hospital, St. Paul's Hospital for Skin and Genito-Urinary Diseases, Hospital for Diseases of the Heart, Westmoreland Street, W., Lock Hospital, and St. Peter's Hospital. After the payment of these and other legacies the residue of the estate is left to such institutions, societies, or nursing homes as assist or provide for persons of moderate means who may not be able or eligible to benefit under the National Health Insurance Act or old-age pensions. Under the provisions of the will of his sister, Mary Ann Clarke, he appoints £9,500 to various hospitals and charitable institutions, and the ultimate residue of her estate is devoted to the Church Army, the West London Hospital, and the National Lifeboat Institution.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology*, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus*, Dublin; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

ANAESTHETICS IN GENERAL PRACTICE.

DR. GEORGINA F. MALDEN (Anaesthetist, Ayr County Hospital and Ayr Maternity Hospital) writes in reply to "M.B.'s" inquiries:

1. The safest and simplest method in anaesthetics is to give chloroform, followed by ether, from a drop bottle on a Schimmelbusch mask, the open method. The mask should be covered with lint, or preferably domette, and the drop-bottles fitted with rubber corks. The anaesthesia should be induced with chloroform, and when fully established maintained with ether, unless specially contraindicated. If the operation is a long one chloroform may be given at intervals during it. It is better not to give a preliminary hypodermic injection of alkaloids if chloroform is to be used. During the past year I have used this method in about 500 cases of every kind, and found it quite satisfactory for both major and minor operations. The amount of ether used is rather large, but decreases as the anaesthetist becomes more skilful.

2. In midwifery I use chloroform only, by the same method, for ordinary operations, such as putting on forceps; for difficult forceps cases and Caesarean section chloroform, followed by ether, given as above.

3. It is possible to use only ether, but the objections are the unpleasant sensations it causes in a conscious patient and the difficulty of obtaining anaesthesia in a powerfully built patient with ether only. Ether must not be used in infants and small children for operations on the throat or mouth, or if a cautery is being used above the level of the patient's hips.

LETTERS, NOTES, ETC.

DR. A. C. MAGIAN of Manchester asks us to state that he is incorrectly described in the current *Medical Directory* as an official of the Manchester Medical Society. The reference, he states, should have been to the Manchester Medical Society, which is not mentioned in the list of

In response to the appeal of the librarian of the British Medical Association in our issue of December 17th, 1921, page 1050, Dr. Samuel Davidson, of Mansfield, Kelso, has been good enough to send Vol. xxxiv of the *Transactions* of the Edinburgh Medico-Chirurgical Society, thus making the series in the library of the Association complete.

OTITIS MEDIA IN INFANTS.

DR. CHAS. J. HILL AITKEN (Kilnhurst, near Rotherham) writes: During the influenza epidemic I visited a baby of 18 months whose symptoms was so indefinite that I labelled the case influenza. At my second visit the mother mentioned that the baby had been putting his hand up to his left ear as if in pain. I ordered wool pledgets with hot oil to be pushed into the meatus. The following day the mother told me the baby had evidently been relieved as he no longer put his hand up to his ear. The baby picked up as one would expect in a case of influenza and then apparently had a relapse. This second stage of the illness continued beyond anticipation and was characterized by no definite locating of symptoms. The marked symptoms were irregular fever, anorexia, sleeplessness, and extreme irritability in a very good-tempered baby. I then read in the BRITISH MEDICAL JOURNAL of otitis media in infants and recommended persistent pushing hot pledgets of oil in the ear—

later the baby was so ill that I had a second opinion and was told there was no sign of ear trouble. Two days later a free discharge came from the left meatus and within a few hours the baby was calling for food and slept quietly for several hours; it has been well ever since; the discharge very soon dried up. Possibly an aural expert might have diagnosed the case earlier, but no aural expert was available.

A SOLUTION OF THE TIPPING PROBLEM.

As is well known, several attempts have lately been made to get rid of the well-nigh universal custom of "tipping" hotel servants. The practice has grown to such a point that in some cases the departure of a guest has come to resemble an escape from a swarm of tax collectors. The managements of leading hotels have long recognized that this state of affairs has become a deterrent to travellers and is a reproach to themselves, and are now trying to modify it. In some cases, especially in Italy, the system has been instituted of charging a fixed percentage on the bill for service and distributing this according to a regularized scale among the staff. This plan has not been entirely successful because every servant knows exactly what he or she will receive, and thus the stimulus of the hope of increased reward from efficient service is eliminated. A medical man, writing from the Winter Palace Hotel, Cimiez, Nice, tells us that this difficulty has been overcome by the management of that hotel. There each guest pays a fixed percentage on his account for service, but for this he is allotted shares in a so-called bonus fund, and these shares he himself distributes among the employees with whom he is brought in contact, in the proportions he thinks they deserve. Thus the stimulus of competition is introduced, because each employee knows that unless the service rendered is good, his or her proportion of the bonus fund will be diminished. This plan appears to work well—at all events, our correspondent tells us that he has never enjoyed more efficient or more cheerful service. Nor do the employees of this hotel accept "tips" in cash. Our correspondent states he has tempted them and failed.

MOTOR CARS: SPARE PARTS.

"M.A., M.D." writes: I note the other day a growl from a fellow practitioner who has been hung up by the "pro forma invoice" nuisance. It is not fair to condemn all English manufacturers, as instance my own experience. I have for the past ten years run a "Standard," and have always experienced the most courteous treatment at their hands. When spare parts, etc., were needed they usually came by return post, and have even been put on the train the same day in response to a wire. The invoice follows later. They are always willing to give full advice either by letter or telephone.

GAMES FOR GIRLS: A DISCLAIMER.

DR. MARGARET G. THACKRAH (London, W.) writes: May I state that the remarks attributed to me, in a report of a meeting which appeared in the *Daily Mail* of January 5th, were those of another speaker? The meeting, which was on the subject of games for girls, was held on January 4th, in connexion with the Conference of Educational Associations, at University College. A shorter report appeared in the *Evening Standard* of January 5th. The statistics quoted were also erroneously attributed to me, the only sentence which was mine being one that referred to the condition of the heart. I should like to say that I entirely dissociate myself both from remarks and statistics.

A DISCLAIMER

DR. W. A. JOLLY, Professor of Physiology in the University of Cape Town, informs us that he has observed that his name is being used by Mr. Mehnarto in Berlin in advertising a serum connected with trypanosomiasis. "This," Dr. Jolly writes, "is entirely without my authority, and in defiance of my warning to him not to make use of my name."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 25, 28, 29, 30, and 31 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 26 and 27.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive posts

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

27. Progressive Muscular Dystrophy.

FRIEDMAN (*Journal, Nerv. and Ment. Dis.*, October, 1921) records a case of progressive muscular dystrophy in which the knee-jerks were absent, the symptoms representing a cross between the Erb type of dystrophy and the Werhig-Hoffman type of progressive muscular atrophy. The attitude and gait, the combination of atrophy and hypertrophy, the absence of fibrillation and reaction of degeneration, and the involvement of the proximal muscles, were characteristic of muscular dystrophy. A boy, aged 16, had had weakness of both legs for fifteen years, with waddling gait and marked lordosis, the chief muscles affected being the left sternomastoid, the right infra- and supra-scapular, the deltoids, the left pectoral and biceps, the erector spinae, the quadriceps and the adductors of the thighs, and the extensor longus hallucis. X-ray examination of the skull was negative, and there was no pitted shadow, but the metacarpal and metatarsal bones were shorter than normal. Blood sugar was normal, and the thymus was not enlarged. There was no response to galvanism or faradism in the quadriceps muscles. The prognosis in progressive muscular dystrophy is good unless the respiratory muscles become involved. The condition has to be differentiated chiefly from polymyositis, in which there is usually pain and no pseudo-hypertrophy; from poliomyelitis, which can be excluded on the history and the electrical changes in the muscles; from congenital muscle defects in which there is no progression; and from myotonia congenita.

28. The Pulse Deficit in the Control of Heart Disease.

LUNDGAARD (*Ugeskrift for Læger*, November 24th, 1921) remarks that practitioners are apt to be overawed by the complicated technique of modern methods in the diagnosis of heart disease and to leave it to specialists. He considers this attitude the more unjustifiable as recent research has added to, rather than subtracted from, the value of simple clinical methods, one of which is the observation of the pulse deficit. This deficit—that is, the difference between the number of pulse and heart beats—can be best determined by two persons, one auscultating the heart the other counting the pulse, while both count by the same watch. The test may be carried out single-handed, the heart and pulse rate being counted in successive minutes by the same person; but though this gives a fairly reliable pulse deficit at rest the pulse deficit after exercise changes too quickly for this single person test to be satisfactory. The author publishes several tables showing the pulse deficit of numerous patients with arrhythmia perpetua, and he points out how misleading and futile it is to control the effects of digitalis by counting only the pulse from day to day. Under digitalis the heart rate may be slowed, but owing to the improved action of the heart a greater number of heart beats will reach the radial pulse, and the observer who relies only on the pulse rate will be misled to think that the digitalis is quickening the heart rate and is doing more harm than good.

29. Dysentery in Vienna.

ACCORDING TO BERNSTEIN, KLING, and ROSENBLATT (*Wien. Klin. Woch.*, November 3rd and 10th, 1921), immediately before the war Vienna, like all large cities in Europe, was practically free from bacillary dysentery, only 70 cases being notified in 1913. In 1914, 1,279 cases were notified in soldiers, and in 1915, 2,075, but the number of notifications rapidly decreased with the progress of the war and the building of field hospitals. After 1916 there was an average of only 300 notifications from the military hospitals to the sanitary authorities. During the first three years of the war dysentery did not spread much among the civilian population, there being about 300 cases in 1914, only 150 in 1915, and 200 in 1916. It was not until the summer of 1917 that the first epidemic of dysentery broke out among the civilian population, 2,229 cases being notified. In the subsequent years fresh epidemics occurred, there being 2,316 notifications in 1918 and 3,355 in 1919. In 1920 isolated cases occurred throughout the winter and spring, the average number of notifications being 20 a month, but the period of fourteen weeks between July 1st and October 14th was characterized by the occurrence of an epidemic wave. In the first week of July there were 9 cases, in the second 73, and the height of the epidemic was reached in the third week of August with 244 cases. In the second week of September the cases had dropped to 72. The total

number of clinical cases in the fourteen weeks was 1,433, of whom 165, or 11.5 per cent., died within these three months and 14 later, making a total mortality of 12.4 per cent. The number of cases between the ages of 1 and 40 was 901, or 61.8 per cent., with a mortality of 4 per cent., while those between 40 and 80 numbered 538, or 35.2 per cent., with a mortality of 21 per cent., thus illustrating the characteristic malignancy of the disease in the second half of life. The writers point out that the endemic occurrence of dysentery in Vienna from which the recent epidemics have originated is the result of want, and can only be successfully combated by improvement of feeding conditions, housing accommodation, and personal cleanliness.

30. Static and Respiratory Displacement of the Normal Kidney.

HITZENBERGER and REICH (*Wien. Klin. Woch.*, November 10th, 1921) state that the question whether the kidneys in health are displaced or not on respiration has received the most contradictory answers, most writers holding the view that these organs are not displaced. Hitherto palpation and percussion have been the only diagnostic methods to settle the matter. The present writers, however, have employed a method which is more reliable than palpation or percussion for determining the static and respiratory displacement of the kidneys. The renal pelvis of a healthy person is rendered visible on X-ray examination by filling it with a 10 per cent. solution of sodium iodide after catheterization of the ureters. On quiet respiration, with the patient in the supine position, there is a striking uniformity in the distance between the renal pelvis and the diaphragm. On changing to the erect position the distance is increased by 10 to 20 mm., showing that the kidney has sunk lower. Both in the recumbent and erect postures the kidney is seen to make definite respiratory excursions which are just as extensive as those of the diaphragm. On deep expiration and inspiration, both in the recumbent and erect postures, the renal pelvis rises or falls to the same extent as the diaphragm, so that the distance between the renal pelvis and the diaphragm remains the same in each of these respiratory phases. The same holds good when the subject distends or retracts the abdominal wall. In patients with enteroptosis the amount of displacement shows such a characteristic variation that even a slight degree of nephroptosis can be detected.

31. Fox and Fordyce's Disease.

BOELSTRA (*Nederl. Tijdschr. v. Geneesk.*, October 29th, 1921) records the first example to be published in Holland of the condition described by Fox and Fordyce in America in 1902, since when about a dozen cases have been reported. The clinical picture is characterized by a typical localization, namely, in the axillae, areolae of the breasts, mons veneris and labia, and in two cases round the umbilicus. With one exception, in which the patient was a young man, all the cases have been found in women, mostly of Jewish or Eastern origin, and of a very nervous disposition. The lesions are formed by minute pruriginous papules on the more or less strongly pigmented skin without lichenification, and consist histologically in hyperplasia of the sweat glands. All the cases, including Boelstra's, which occurred in a very nervous woman, aged 19 (not a Jewess), proved extremely refractory to treatment. The condition is usually classified as a necrodermatitis.

32. Circumscribed Bromide Eruption.

PULVIRENTI (*Il Policlinico, Sez. Prat.*, October 24th, 1921), who records an illustrative case, remarks that though the use of bromides in large doses and for long periods is frequent, especially in epilepsy, bromide eruptions are comparatively rare, so that predisposing causes must obviously be responsible for their occurrence. Age has a certain importance, for though the eruption may occur in children, it is much more frequent in adults, and particularly in old persons. Chronic cardiac, renal, or pulmonary disease, and alcoholism often figure in the history. Writers usually attach much importance to the functional condition of the gastrointestinal canal, and especially the stomach and the diet. Pulvirenti's case occurred in a woman aged 26, who had suffered from epilepsy since puberty. She had been taking bromides from the age of 15, and for the last three years in doses of 1 to 2 grams a day. There were no general causes, such as cardiac, renal, or pulmonary disease, to account for the eruption, which appeared in the middle third of the left

leg, but the localization was attributed to a recent scald. Similar cases of circumscribed bromide eruption have developed round varicose veins (Hallopeau and Viellard), at the site of a scar (Giovannini), or in the neighbourhood of vaccination cicatrices (Crocker), bed-sores (Lucchetti), or contused wound of the leg (Lucchetti).

33. Value of Butter-flour Food in Infancy.

GRIFFITH (*Therapeutic Gazette*, November 15th, 1921) calls attention to the value of the Czerny-Kleinschmidt "butter-flour" food in the feeding of premature, or underweight, infants without any active digestive symptoms. Based on an attempt to approximate the composition of human milk, the preparation is made by using 2 tablespoonfuls of melted butter, 2½ level tablespoonfuls of flour, 1½ level tablespoonfuls of cane sugar, and 10 fluid ounces of water. The melted butter is heated over a fire for from three to five minutes until foaming occurs and all odour of volatile fatty acids disappears, and this is then mixed with the flour, and the mass again boiled, with constant stirring for from four to five minutes, until it becomes thin and brownish. After adding the water and sugar the mixture is again boiled, rubbed through a fine sieve, and then mixed with the desired amount of boiled and cooled milk and the whole kept in bottles till required. The proportions for children under 3,000 grams in weight should be one-third milk to two-thirds butter-flour mixture, and for those over 3,000 grams two-fifths and three-fifths of the butter-flour stock are used. Not more than 3 fluid ounces per pound should be given daily, and usually small amounts are required on account of the high caloric value of the food. Results were remarkable, the steady gain in weight, and the improvement in general appearance, colour, and fat distribution resembling that seen in breast-fed infants.

SURGERY.

34. Treatment of Gonorrhoea by Cedarwood Oil.

LAUTIER (*Bull. Soc. de Thér.*, October 12th, 1921) has treated cases of acute and chronic gonorrhoea, with or without prostatitis, cystitis, vesiculitis, and orchio-epididymitis, by administration of cedarwood oil. The doses ranged from 2 to 8 grams a day. The dose was at first 2 to 3 grams, and was gradually increased to 25 to 50 cg., the maximum dose being continued until recovery was complete—that is to say, when the following requirements were fulfilled: (1) Disappearance of all discharge; (2) disappearance of all ailments in the first jet of urine passed on getting up in the morning; (3) disappearance of all subjective symptoms in the patient. Lautier's conclusions are as follows: (1) Cedarwood oil was very well borne by the patients, even in such large doses as 6 to 8 grams a day. It did not cause any digestive disturbances, lumbar pain, or albuminuria, which cannot always be avoided even with the purest sandalwood oil. No nervous symptoms were ever observed, such as vertigo, headache, excitement, or depression. (2) In acute gonorrhoea the various oils of cedarwood have a rapid action, a cure being all the more readily obtained the earlier treatment is commenced. The previous use of antiseptics appeared to delay recovery. (3) In cases of gonorrhoea treated exclusively by cedarwood oil from the commencement of the disease no urogenital or general complications were ever observed. (4) In cases of old-standing gonorrhoea which were refractory to all other treatment a very rapid cure was sometimes obtained by the use of cedarwood oil. In other cases it had to be given regularly for one and a half to two months to obtain a permanent cure. A few chronic cases proved refractory even to large doses of cedarwood oil. These failures were exceptional with the oil of *Juniperus virginiana* or *bermudiana*, and more frequent with the oil of *Cedrus atlantica*. (5) In cases of prostatitis, cystitis, vesiculitis, and orchio-epididymitis a rapid cure was obtained except in cases where the gonococcus was associated with other micro-organisms, when 1 or 2 grams of hexamethylenetetramine were required to obtain a satisfactory result.

35. Cranioplasty with Bone Grafts from the Tibia.

ROCHER (*Gaz. hebdom. des Sci. Méd. de Bordeaux*, October 23rd, 1921) describes his technique—a modification of that adopted by Delagenière—for closing gaps in the skull by means of osteo-periosteal grafts removed from the tibia. He has carried out this operation on forty-three occasions. The number of grafts used varied with the size of the defect to be closed; as many as five have been employed. He lays stress on the following points: (1) Local anaesthesia with cocaine and adrenaline should be used. With general anaesthesia venous haemorrhage was troublesome and a haematoma developed under the graft and caused an epileptic fit the same

night in one case. (2) The excision of the painful scar and freeing all parts adherent to the meninges, as these may cause the starting point of future troubles. (3) The graft is taken from the inner surface of the tibia. It consists of both bone and periosteum, being 1 mm. in thickness, and is removed with a sharp chisel, taking care that the bony surface is quite smooth. It is modelled with forceps to the curvature of the skull, and is never touched with the fingers during these manipulations. The grafts are fixed side by side and under the periosteum of the skull, being held in place with a few catgut sutures. Drainage is avoided if possible. Rocher never uses more than a single thickness of graft to fill up the gap and places the bony surface of the graft towards the brain. Delagenière advises that the periosteal surface should be turned towards the brain to avoid possible compression or irritation of the brain from overgrowth: in the light of experience this does not appear to take place. He states that the aesthetic results have been excellent, and the headache, feeling of dullness, and other troubles present before operation, have, in most cases, rapidly improved or disappeared. The operation does not claim to cure all the troubles of the trephined, but it has a threefold value: aesthetic, preventive of external trauma to the trephined area, and curative in restoring the normal intracranial pressure. The closure of the gap by the graft is rapid, and at the end of fifteen days it is fixed firmly in position. When practised in young subjects cranioplasty is satisfactory and no subsequent trouble has been caused by the graft.

36. Chronic Cystic Mastitis and Carcinoma.

LUKOWSKY (*Deut. Zeit. f. Chir.*, Bd. 167, Heft 1 and 2, 1921), after a review of the literature and a record of twelve cases examined at the Pathological Institute of Cologne University, comes to the following conclusions: (1) Diffuse mammary fibromatosis or chronic cystic mastitis is neither a true tumour nor an inflammatory process, but a chronic irritative condition accompanied by abundant growth of connective tissue, involution processes, and proliferation of epithelium. The primary change is hyperplasia of the connective tissue. (2) The formation of cysts is a secondary phenomenon. It originates from constriction of the acini by the growth of connective tissue and the retention of a pathological secretion. Proliferation of epithelium, which occurs relatively late and is therefore to be regarded as secondary, may possibly be explained by the irritation of the retained secretion. (3) Carcinoma readily develops in diffuse mammary fibromatosis, either from the epithelium of the efferent ducts or from the acini, the frequency of this complication, according to various writers, being 7 per cent. (Schimmelbusch), 15 per cent. (Theile), 45 per cent. (Morris Wolf), and 50 per cent. (Bloodgood). The existence of carcinomata can only be proved by the presence of destructive growths, and not by the structure of the cells. Destructive growth, however, may be detected at an early stage, either in relation to the surrounding connective tissue or the adjacent epithelium.

37. Hydrocele of the Kidney.

KROGIUS (*Finska Läkarsällskapets Handlingar*, September and October, 1921) describes a condition which has been variously termed "hydronephrose externe ou sous-capsulaire," "perirenal hydronephrosis," "perinephritis scrota," or "hydrocele of the kidney." The term "perirenal hydronephrosis" is misleading, as it suggests that the fluid surrounding the kidney consists of urine. From the scanty records of these cases it is impossible to obtain a clear conception of their etiology, but in some cases it would appear that it is provoked by stasis in the lymphatic system. In one case, recorded by Minkowski, complete recovery was effected by simple incision of the renal hydrocele and packing the cavity with a tampon. This simple operation is therefore indicated in cases uncomplicated by hydronephrosis or other morbid conditions. In the author's case the patient, aged 67, suffered also from cancer of the uterus, and the large renal hydrocele was associated with a moderate degree of hydronephrosis.

38. Congenital Perineal Ectopia of the Testis.

DANGSCHAT (*Deut. Zeit. f. Chir.*, August, 1921) records a case of perineal ectopia of the right testis in a man, aged 50, in whom death was due to cancer of the rectum. The author holds that perineal displacement of the testis differs from inguinal displacement in that whereas atrophy is almost the rule in the latter, and is even visible to the naked eye, the perineal testis is almost invariably of normal size, as in the present case. Although numerous histological studies have been made of the inguinal testes, showing atrophy of the seminal tubules and complete absence of spermatogenesis associated with a predominance of the interstitial cells, hardly any microscopic examinations have been made of

the perineal testis. A. Ledwich, the only previous observer who has made a microscopical examination of a perineal testis, found that the procreative power of the organ had not suffered from its displacement, and that the function of the cells was quite normal. His investigations were confirmed by those of Dungschat, who found that the structure of both testes was the same. As regards the occurrence of malignant degeneration, no example of a malignant growth has yet been observed in a perineal testis, whereas this is by no means a rare event in inguinal testis. This has been attributed by Inott to the greater richness of the inguinal testis in interstitial tissue, which in the perineal testis is not more abundant than in the normal organ.

39. Urinary Calculus.

HOMERSON (Nat. Med. Journ. of China, September, 1921) reviews the experience gained in the treatment of urinary calculi at the Canton Hospital, based upon 3,500 operations. For the general surgeon, with comparatively small experience in this work, cystotomy is the operation of choice, but in each case the age, general condition of the patient and of the urinary tract, and the size, consistency, and mobility of the stone, have to be taken into consideration. Cystotomy can be performed rapidly with comparative safety, and it is the operation of necessity with large hard stones, abnormalities, disease of the urethra, prostate, or bladder, and in young persons. Recurrence is rare, and the operative mortality in uncomplicated cases was 3 per cent. Median or lateral perineal section is the operation of choice for medium-sized stones impacted in the perineal urethra, and the mortality in uncomplicated cases was 3.8 per cent. Litholapaxy requires technical skill, and is indicated for small hard stones in adults whose urinary passages are otherwise healthy. Recurrence is more frequent than with cystotomy or the perineal operation, and the mortality in uncomplicated cases was 4.4 per cent. In females small calculi may be extracted per urethram, and primary union may be expected after suprapubic lithotomy if the bladder is closed. Vaginal cystotomy is contraindicated on account of a possible resulting fistula. In dealing with urethral calculi the bladder should always be sounded, cystoscoped, or x-rayed or possible vesical stones.

40. Thyroid Malignancy with Secondary Deposits in Bones.

ENORMANT (Bull. et Mém. Soc. Méd. des Hôp. de Paris, December 6th, 1921) refers to the case of a woman, 53 years of age, with a goitre, living in a district where goitres were common. The enlargement in her case was slight until at the age of 48 years it became larger and caused difficulty in breathing, with attacks of dyspnoea. Later she suffered from pain and swelling of both arms, and finally loss of use of the left arm. There was also found a tumour, the size of a pigeon's egg, arising from the manubrium sterni. Radiographic examination showed that the tumours of the arms rose from both humeri, and caused extensive destruction of bone. Later there was spontaneous fracture of both bones. Microscopical examination of a portion of the enlarged thyroid showed that it had the definite characteristics of malignancy, whilst examination of a portion of the deposit in the humerus proved it to be a colloid carcinoma. He points out how in his case a slightly enlarged thyroid had for over thirty years all the appearances of being a benign goitre, until the menopause was reached; then it commenced to grow and to cause symptoms of respiratory distress. This increase in size of the thyroid after years of complete tolerance is characteristic of malignancy, as Kocher has shown. Every goitre which, in an adult, gets larger without reason or cause should be suspected of malignancy if there is neither haemorrhage nor inflammation present to explain this change. Metastases in bone are common in thyroid malignancy, and manifest themselves during life by paraplegia when arising in the spine, or by spontaneous fracture when occurring in the bones of the limbs. Leuonmant doubts whether a benign goitre ever gives rise to metastases in the skeleton, and considers that every tumour of the thyroid which gives rise to secondary deposits in the bones is carcinomatous.

41. Thrombophlebitis of the Cavernous Sinus of Dental Origin.

AURET (Paris méd., October 15th, 1921), who records a fatal case of a girl, aged 7½ years, remarks that propagation by the veins to the cranial sinuses and meninges of an ordinary dental infection, though by no means common, is worthy of attention on account of its gravity. Delay in operating and stagnation of pus play an important part in the pathogenesis. Early and energetic treatment is required on the first mani-

OBSTETRICS AND GYNAECOLOGY.

42. Coexisting Uterine and Ectopic Gestation.

ACCORDING TO STROPENI (*Annali di Ostetricia e Ginecologia*, November, 1921), the occurrence of gestation in both uterine and Fallopian tube at the same time is not very infrequent, although five or six instances only have been recorded in the literature since Nungebauer, in 1913, collected 243 cases. In about one-third of these cases the uterine pregnancy continued to term, in spite of the performance in many instances of laparotomy and removal of the ruptured or intact extra-uterine gestation sac. Since tubal abortion or rupture is accompanied by uterine contractions there is, however, a greater chance of survival of the uterine embryo if the operative intervention takes place at a time antecedent to that of such abortion or rupture. Stropeni relates the case of a primipara, aged 37, who after seven weeks' amenorrhoea suffered from acute abdominal pain. Her general condition, at first critical, underwent slow improvement as a haematocoele was formed in the pouch of Douglas, but in the course of a few weeks operation became necessary on account of subacute intestinal obstruction. Removal of the blood clot from the pelvis, together with ablation of the ruptured gravid tube, were followed by speedy recovery. The early uterine pregnancy was not noticed at the time, but becoming manifest in the next weeks continued to full term and led to the birth of a hydrocephalic dead foetus weighing 3,700 grams. With regard to the principles of treatment of coexisting uterine and extrauterine pregnancy, the author is in accord with Blicht and with Costa in advocating (1) in cases in which both embryos are living but the gestations are of the earlier months, ablation of the ectopic gestation sac; (2) when the extrauterine foetus is alive in the later months of pregnancy, expectant treatment followed by laparotomy at the commencement of labour; (3) in cases in which the ectopic foetus is dead, treatment according to the ordinary methods used in simple extrauterine pregnancy. There is no recorded instance in which adhesions consequent on rupture of ectopic gestation have interfered with the normal course of labour at the termination of the uterine pregnancy.

43. Rapidity of Development of Uterine Myomata.

ACCORDING TO GRAEBKE (*Zentralbl. f. Gynäk.*, October 22nd, 1921), precise data as to the rate of development of uterine myomata are few. The chief governing factors are the histological structure of the tumour and hormonal ovarian influences; in addition, factors which, like pregnancy or treatment by diathermy, lead to increased pelvic blood supply may cause increasingly rapid growth of myomata. Cancer of the uterus is, as a rule, associated with diminished rapidity of growth in pre-existing myomata. The author relates the case of a 13-para, aged 48, who suffered from uterine haemorrhage of three months' duration, and was found by examination under a general anaesthetic to have a uterus which, although somewhat irregular in consistency, was scarcely enlarged, contained no palpable tumour, and freely admitted the sound for a distance of 9 cm. The histological examination of the scrapings confirmed the diagnosis of chronic endometritis, and x-ray treatment was carried out with a view to inducing sterilization and amenorrhoea. The haemorrhage persisted in greater or less degree during the ensuing three months, at the end of which the uterus exhibited a solid enlargement palpable above the symphysis pubis, and a fibroid polypus (weighing after removal 35 grams) presented in the vagina. Four months later the uterus had become smaller, and the patient was free from pain or haemorrhage. In explanation of the rapid increase of the uterine myomata following x-ray treatment it is suggested that the ovaries of this patient, who had borne thirteen children, were anasally active, and that the initial stimulating effect of the irradiation was to increase the production or absorption of ovarian internal secretion, and thus to cause increased activity in the tumour tissue.

44. X-ray Treatment of Uterine Fibroids.

BÉCLÈRE (*Journ. de radiol. et d'électrol.*, October, 1921), who two years previously had reported his observations on 400 cases of uterine fibroids treated by radiotherapy, gives the following account of 300 more cases which he had treated in the same way. Forty-eight, or 16 per cent., of the patients were aged 50 years and upwards; 205, or 67.66 per cent., were aged between 40 and 49; 48, or 16 per cent., between 30 and 39; and 1, or 0.33 per cent., was under 30. In 124 cases, or 8 per cent., the tumour was intrapelvic, and in 276, or 92 per cent., it was abdominal; 157, or 57 per cent., of these abdominal tumours, reached or exceeded a level of 10 cm. above the pubis, and 8 at least by extending 25 cm. above that

entitled to be called "giant tumours." In the majority of patients the predominant symptom was more or less profuse, prolonged, and regular metrorrhagia. The size of the uterine tumour, its protrusion and rapid growth, as well as the compression of the bladder, were especially the chief. The two principal results of treatment were, first, the disappearance of metrorrhagia, and suppression of menstruation in the 294 patients who had not yet reached the menopause, and secondly, a more or less rapid and pronounced diminution in size of the uterine tumour in all the patients treated. In 81 per cent. of the cases the monthly periods did not reappear more than twice before they finally ceased. Among the 294 patients who had not reached the menopause there were only 10 cases of relapse, or a proportion of 3.40 per cent., the periods returning after amenorrhoea of from three to sixteen months' duration; in only 3 cases, or 1 per cent., did the treatment fail, subtotal hysterectomy being required. The only contra-indications to a-ray treatment, according to Bécère, are septic complications, suppuration, and gangrene, which require immediate operation.

45. The Corpus Luteum in Diagnosis and Therapeutics.

DOLANSKY (*Casopis lékařů českých*, 1921, 6), in 191 cases of metrorrhagia or metrorrhagia, has made subcutaneous injections, repeated if necessary at daily intervals, of portions of the fluid removed from a corpus luteum cyst of the human ovary. He claims that, in cases in which the haemorrhage comes to a standstill after one to five injections, the bleeding may be regarded as having been due to causes connected with the internal secretion of the ovary. The cases in which the bleeding was not affected numbered 32, including 11 tuberculous or syphilitic, 6 of malignant disease, and 9 of pregnancy. Of the remaining 159 cases which reacted successfully 29 were instances of haemorrhage at or shortly after puberty; permanent cure was established after five injections at most. Forty-five cases (corresponding to cases of endometritis, or metritis according to the more usual nomenclature) of "ovarian" bleeding occurring in the absence of pelvic inflammation during the period of sexual activity became cured with equal speediness and a similar lasting effect. In 11 cases of "ovarian" bleeding associated with pelvic inflammation the injections were followed by a subjective betterment and by temporary cessation of the haemorrhage. Thirty-one cases of haemorrhage of the climacteric were brought to a temporary standstill after the injections, and injections given three or four days before the expected onset of a haemorrhage appeared to modify its characters so as to make them resemble those of a normal menstruation. The author attaches much diagnostic significance to the mode in which haemorrhages of doubtful etiology respond to an injection of corpus luteum cyst fluid: in cases in which there is a suspicion of malignant disease the failure of such injections to control the haemorrhage is a sign that the bleeding is not of ovarian origin and confirms the necessity for the removal of a specimen for microscopic examination.

PATHOLOGY.

46. Pathological Anatomy of Influenza.

DURING the influenza epidemics of 1918-19 and 1921, LLAMBIAS and ELIZALDE (*C. R. Soc. Biologic*, November 26th, 1921) conducted 91 *post-mortem* examinations on patients who had died with pulmonary lesions. Amongst these were 45 with pneumonia, 52 with bronchopneumonia, 19 with pleural effusions, 5 with acute endocarditis, and 6 with pericarditis. After enumerating a series of lesions affecting certain organs, they draw attention to some of the features which appeared to be peculiar to the epidemic. Of such are the following: The abundant sero-sanguineous exudate in the lungs affected with pneumonia and bronchopneumonia; the distinctly haemorrhagic tendency of the fluid exudates in the early stages; the frequent parenchymatous degeneration and necrosis; the presence of infarcts of various sizes in the lungs due to local thrombosis; the generalized subpleural capillary haemorrhages; and the large number of cases exhibiting parenchymatous degeneration of the liver, heart, kidneys, and suprarenals.

47. Vaccination against Bacillary Dysentery.

VINCENT (*C. R. Soc. Biologic*, November 26th, 1921) gives the results of a fairly extensive trial of vaccination against bacillary dysentery, conducted on a series of 2,175 individuals. During the progress of an epidemic due to the *B. dysenteriae* Shiga, prophylactic inoculation was commenced, the vaccine used being a polyvalent one. As a result the number of cases developing the disease was reduced to a proportion of 1.6 per cent. in the vaccinated as compared with one of 22.8 per cent.

in the uninoculated controls. In a subsequent epidemic, apparently due to a mixed infection with the Flexner and the Shiga types of dysentery bacilli, a polyvalent vaccine containing 2,000 million organisms per cubic centimetre was administered to a part of the population, with the result that the morbidity in the vaccinated was only 0.8 per cent., as against one of 7.1 per cent. in the unvaccinated. Further, while the mortality in the latter was 0.16 per cent., amongst those who had been inoculated there were no deaths at all. Unfortunately the total number of patients involved in this outbreak is not recorded.

48. Rheumatic Myocarditis.

HOLST (*Norsk Mag. for Lægervidenskaben*, December, 1921) has examined clinically and after death the hearts of 66 patients, 7 of whom died during or shortly after an attack of acute rheumatic fever. The *post-mortem* examinations of these hearts were conducted on Krehl's lines, and the systematic microscopic sections showed typical Aschoff-Tawara nodes in 4 of the 7 hearts. In the remaining 3 there were definite signs of myocarditis with round-cell infiltration. In none of the other 59 hearts could Aschoff-Tawara nodes be found, and though the author admits that their relation to the virus of acute rheumatism is not yet established, he is inclined to regard them as the foci from which new attacks of acute rheumatism start. They would thus be comparable with tubercles and latent foci of syphilis, and acute rheumatic fever might be regarded, not as an acute short-lived disease, but as a chronic disease with acute exacerbations. If this view is correct, the disease would best be combated by systematic, intermittent, specific treatment with salicylates, even in the intervals between acute exacerbations, just as syphilis is treated. The author considers rheumatic myocarditis to be a comparatively common condition, although it is practically impossible to diagnose it with certainty during life, and even after death the diagnosis cannot be made without the microscope. His opinion of digitalis in acute rheumatic myocarditis is not favourable.

49. Experimental Mumps Meningitis.

MENINGO-ENCEPHALITIS is an occasional complication of mumps in the human being. WOLLSTEIN (*Journ. Exper. Med.*, December, 1921) has been successful in reproducing this condition in cats by the intrathecal inoculation of the sterile filtrate from the combined mouth washings of four children on the second and third days of a typical attack of parotitis. The day following the injection the cat developed strabismus; subarachnoid occipito-atlantoid puncture withdrew turbid fluid under greatly increased pressure, which on examination was found to contain a large amount of globulin, 22,000 cells per cubic millimetre, of which 84 per cent. were polymorphs and 16 per cent. mononuclears. Bacteriologically the fluid was sterile. After lasting for five days the condition cleared up and the cat recovered. Another cat, similarly injected, was chloroformed on the third day. *Post-mortem*, the pia was cloudy and oedematous and the vessels deeply congested. No organisms could be grown from the brain. It was further found possible to transfer this condition from one cat to another. Three control animals remained unaffected. As to the exact nature of the original substance in the salivary filtrate which gave rise to the aseptic meningitis—whether of toxic nature or of the nature of a filter-passing virus—no experiments are recorded and no opinion expressed.

50. Rickettsia in Lice Fed on Cases of Typhus Fever.

RICKETTS and WILDER in 1910 noticed the presence of small bipolar micro-organisms in the bodies of lice fed on cases of typhus fever. Since that date similar bodies have been encountered in lice from cases of trench fever and of Rocky Mountain fever. These have been given the general name of Rickettsia. SERGEANT, FOLEY, and VIALATTE (*Arch. des Instituts Pasteur de l'Afrique du Nord*, September, 1921) now recall the fact that in 1914 they also were able to substantiate the presence of similar organisms in lice taken from cases of typhus fever occurring in two epidemics situated at a distance of 900 kilometres from one another. In size they vary from 0.2 μ in diameter to 3 μ . They show bipolar staining and are arranged singly, in pairs, or in short chains. Lice taken from patients in the incubation stage of the fever are free from these bodies; during the first few days of the illness only a small proportion are infected, while those examined between the twentieth and twenty-fifth days are found to be heavily infected. In this stage they are able to transmit the disease to healthy men and monkeys. Further, the infection appears to be capable of being handed on hereditarily to the offspring of the lice. Amongst the several thousand lice coming from healthy persons which they have dissected during the past ten years no such bodies have ever been found. The exact part that these micro-organisms play in the etiology of typhus fever is as yet unknown.

A British Medical Association Lecture ON THE POSITION OF THE THYROID GLAND IN THE ENDOCRINE SYSTEM.

BY
N. LANGDON BROWN, M.A., M.D. CANTAB., F.R.C.P.,
PHYSICIAN WITH CHARGE OF OUT-PATIENTS, ST. BARTHOLOMEW'S
HOSPITAL; PHYSICIAN TO THE METROPOLITAN HOSPITAL.

W subjects in medicine have so powerfully stimulated crest and imagination of recent years as endocrinology. It provides the missing link between biology and psychology. It has profoundly modified our conception of disease. The endocrine secretions result from the specialization of the old unicellular stimuli to which primitive animals reacted even ere there was a nervous system at all. They reveal their identity in the way they cling to vestigial structures. Not recently when in the course of evolution a structure has become useless for its original purpose the endocrine system applies it with a new tenant. Thus, the thyroid probably represents the Palaeozoic gill-slits, the parathyroids and sinus originate from the now useless gill-slits, the pituitary represents an invertebrate kidney, and the pineal an invertebrate eye. They remind us of the hermit crab that clings on an empty whelk shell. And just as the hermit crab is ousted before it found an empty house, so the endocrine secretions were in existence before they had a local habitation. This is particularly well seen in the primitive chromaffin material, which was originally widely diffused throughout the body of lower animals, before becoming concentrated in the renal medulla.

Internal secretions regulate instinctive behaviour. When the gonads of the queen bee reach a certain stage of development they render her strongly heliotropic. Hence the flight. The immediate effect of fertilization is to destroy this heliotropism, and she seeks the shelter of the nest. So with human beings. The instinctive behaviour of young man in the presence of the opposite sex, whether shy or aggressive, depends mainly on the state of his endocrine system, and the unreasoning fractiousness of the maturing woman merely reflects the chaos into which this system falls when its keystone is displaced. In this connexion it may be pointed out that the influence of these glands on secondary sexual characters is rather complex. The man with hyperthyroidism shows feminine traits, hyperpituitarism leads to virilism, hypopituitarism to feminism; and increase in the adrenal cortex, while producing premature sexual development in children, leads to marked virilism in women. According to Blair Bell, all the endocrine glands acting in harmony control metabolism in accordance with the needs of reproduction, and adapt the whole organism, physically and psychologically, to this end. These few examples will illustrate what may happen when harmony is replaced by discord. The endocrines not only develop some characteristics, but they repress others. Without following Bolk to all his conclusions, I should agree that certain monkey-like traits are kept in abeyance by the pituitary. When this is diseased, as in acromegaly or osteitis deformans, the reversion to a monkey-like aspect is obvious. It is also known that when the pineal is diseased there is sexual precocity. Bolk suggests that the present function of the pineal is to delay sexual maturity in the interests of a more prolonged somatic development, for in the higher species the individual counts for more and fertility for less.

The activities of the endocrine glands are correlated to a large extent through the nervous system. We are so much more conscious of what goes on outside than of what occurs inside us that when we speak of the nervous system we are apt to think of it only in terms of the sensorimotor structures which keep us in touch with the external world. But for the maintenance of our vital functions we depend much more on the autonomic nervous system—and it is this system which has entered into an alliance with the endocrine glands.

b

THE AUTONOMIC NERVOUS SYSTEM.

The autonomic, vegetative or visceral nervous system consists of two great divisions, the sympathetic and the parasympathetic or extended vagus. The former is katabolic,

converting potential energy into kinetic and facilitating outward manifestations of that energy, while the latter is anabolic, directing energy inwards where it is stored up. When these two are distributed to the same structure their action is always antagonistic, and when one is stimulated the other is inhibited. The rhythm of life depends largely on the fluctuating balance between these two. The parasympathetic plays the chief part in the digestion and assimilation of food, the sympathetic spends the energy thus derived. In sleep the parasympathetic gains control, and the arrest of external manifestations of energy lasts until the balance is restored in favour of the sympathetic, when the subject awakens ready to expend energy again.

Each of these great divisions co-operates with a group of endocrine glands—the sympathetic with the adrenals, thyroid, and pituitary, the parasympathetic mainly with the glands of the digestive organs and their annexes. Possibly the parasympathetic co-operates also with the parathyroids. The autonomic nervous system is pre-eminently defensive in its action. In the primitive animal either the parasympathetic may be brought into play when the shock to which it is exposed is very great, producing immobility—the “shamming dead” reflex—or the sympathetic may be stimulated, violently activating the body for flight or fight. It is important to note that either this or that result follows without any attempt at compromise between the two, which Sherrington has shown is typical of reflex action in general.

But the sympathetic nervous system is a defensive mechanism not only against the external, but also against the internal foe. Fever is a response to bacterial invasion, and we now know that it is produced peripherally rather than centrally, since the cerebral vessels are remarkably impermeable to drugs and toxins so long as they remain intact. And this is carried out by the thyroid and adrenals, possibly with the aid of the pituitary. Fevers are known to be followed by changes in the adrenals and thyroid, but Cramer has been able to show that anything which calls for increased production of heat definitely increases the secretory activity of these glands. Mere exposure of a mammal, though not of a cold-blooded animal, to a low temperature will effect this. The injection of the drug known as T.H.N. will produce similar changes, together with all the phenomena of heat-stroke, and only exposure of the injected animal to cold will prevent a fatal issue. He has found similar changes in hyperpyrexia, and to a less degree in all fevers. He regards the heat regulation of the body as mainly effected peripherally, and points out what a profound effect climatic must therefore have on the endocrine glands. Indeed, when one compares the brain, rigidly shut off in its bony box, with the peripheral apparatus in the skin, possessed of sensitive end-organs, responsive blood vessels, and sweat glands, together with the power of acquiring protective pigment, the case for a peripheral regulation of the temperature becomes so plausible as to cause wonder at its being overlooked so long. This was, no doubt, because it was so difficult to see how sufficient co-ordination could be obtained, as long as the close ties between skin, sympathetic nervous system, and endocrine glands were not appreciated.

Leonard Williams some twelve years ago called attention to the influence of climate in moulding racial character through the endocrine glands, but his conception was too much in advance of current medical thought then to receive the attention it merited. He pointed out that not only are there differences between the white man and the black, between Asiatics and Europeans, between the Latins and the Saxons, admittedly and even obtrusively climatic in origin, but that modifications through climate can still be seen at work. He says: “In illustration of the last point I need only mention the fair skin and the red hair which long residence in northern climes has conferred upon some Jewish families, and the stereotyping by the climate of the North American continent of the descendants of its widely dissemblant annual European recruits into the hatchet-shaped face and vire form of the Red Indian aborigines.” He suggests that the skin may be compared to a sensitive plate, stimulation of any portion of which will produce reflex activities in some distant organ, and he regards the formation of cutaneous pigment as protective against such stimulation becoming excessive. The distant organs mainly affected in this way he believes to be the endocrine glands, and it is obvious that the adrenals, for instance, play an important part in the pigmentary changes in the body. Recent observations show the pituitary must share directly in this, since tadpoles that had the anterior lobe of that gland removed became albinos. The adaptation

THE THYROID AND THE ENDOCRINE SYSTEM.

[THE BRITISH
MEDICAL JOURNAL]

ability of albinos to climatic changes is well known. At the time the theory was put forward the close association between the sympathetic-endocrine system and the higher levels of the nervous system was not sufficiently recognized to make it acceptable. But I think we are now justified in saying that climatic environment can modify our psychic "make-up" through the endocrine glands.

HYPOTHYROIDISM.

These preliminary considerations will enable us to realize the position of the thyroid gland in the endocrine system. Says McCarrison: "The thyroid gland is to the human body what the draught is to the fire." It is a quickener of the whole metabolism. Recent studies of basal metabolism have shown that in hypothyroidism this is lowered by 40 per cent., while in hyperthyroidism it may be raised by an even greater amount. Although severe degrees of hypothyroidism, such as myxoedema and cretinism, are well recognized, there are minor degrees, as pointed out by Hertoghe, which are unfortunately often overlooked, although they are ominously amenable to treatment. In the adult these are characterized by the accumulation of material which should be katabolized. Headache, giddiness, somnolence, and a sense of fullness in the ears and nasopharynx, are not uncommon. A number of manifestations of hypothyroidism are attributed to rheumatism, although really due to myxoedematous infiltration of ligaments and fasciae, producing knock-knee, painful heel, flat-foot, and lordosis. The hand becomes lax and flabby, feeling, as Hertoghe says, like a glove stuffed with clay. A very helpful sign of hypothyroidism is the disappearance of the outer half of the eyebrows. The association of this with "rheumatic" symptoms should suggest the administration of thyroid extract. Nocturnal enuresis has been shown to be sometimes due to the same cause, partly because desquamation of the epithelium of the bladder renders it more irritable, and partly because of the deep somnolence. Infiltration of the nerve centres causes mental slowness, loss of memory, and difficulty in expressing ideas. Sometimes there are hallucinations of sight and hearing. It is rather surprising that acute mania should occur in myxoedema, but it does so occasionally. I recently saw an example in a middle-aged man whose myxoedema had improved extraordinarily under thyroid extract. Unfortunately he abandoned medical treatment and took up Christian Science. He became violently maniacal, and was removed to an asylum. Here they recognized that he was suffering from myxoedema, but at first they were afraid to give him thyroid extract because of his maniacal condition. But when they did so he again improved rapidly, and was soon able to give his medical history. He is now quite sane.

HYPERTHYROIDISM.

Turning to hyperthyroidism it is convenient, as McCarrison does, to classify the influences leading to it under the three heads of nutritional, toxic, and psychic.

(1) Nutritional.

Lack of vitamins leads to diminished thyroid secretion (McCarrison). Mellanby has suggested treating Graves's disease by cutting off the fat-soluble vitamin from the diet, but I have not been much impressed by the results of this method. Under the nutritional heading we may also include some part of the epochal changes in the gland, such as is so common in girls at puberty. In this connexion I should like to call attention to the importance of a small or twisted upper lateral incisor as evidence of gonadal deficiency. It is difficult to see the connexion until we recall that this condition of the incisor is the slightest degree of cleft palate. It is an atavistic stigma, and implies a difficulty in establishing adult development. This may explain why, as I have observed, such patients are liable to undue enlargement of the thyroid at puberty, since it is apparently more of a strain for them to achieve maturity.

(2) Toxic.

Two sources of toxæmia seem particularly apt to produce thyroid enlargement—namely, intestinal and oral. We can understand why intestinal toxæmia has this effect, since Kendall has shown that the active principle of thyroid secretion is an iodine compound of indol, a putrefactive decomposition product of the tryptophan in the protein molecule. It would appear as if the body provided in this way its own antidote, an increased production of indol necessitating and providing for more thyroid secretion. Quite as striking is the influence of oral, particularly

tonsillar, sepsis. It is hardly too fanciful to connect this with the fact that the thyroid gland originally discharged its secretion into the mouth through the foramen caecum at the base of the tongue. Since thyroid secretion is evidently increased by reaction to bacterial infections, an infection near to the point at which this secretion was originally discharged might be expected to be specially potent in this direction.

A few weeks ago I had a case in hospital of recent and severe thyroid enlargement in a lad of 17. The gland formed a tense collar from the jaw to the clavicles, and his neck measured 20 inches in circumference. I was afraid that he might have sarcoma of the thyroid, but Mr. Dunhill, who kindly saw him with me, thought it was probably subacute thyroiditis. His tonsils appeared septic, but before they could be enucleated he had an attack of tonsillitis, after which the gland rapidly subsided, so that in a few days the neck measured only 17 in. The tonsils were then enucleated by Mr. Harmer. X rays were applied to the gland and rapidity. It should be added that he showed no ocular signs, tachycardia, or tremors. His increased thyroid secretion had apparently been needed to combat the sepsis. Squier has commented upon the rapid subsidence of thyroid enlargement after an acute infection, which he attributed to diminution of secretion through post-infective sclerosis of the gland. Of course, other septic causes may induce thyroid enlargement besides these two, and I recently saw a case of Graves's disease following pericarditis. Indeed, Walter Edmunds speaks of the toxin of acute rheumatism as one of the recognized causes of Graves's disease. But, after all, there is a good case for regarding acute rheumatism as due to alimentary streptococci of altered virulence.

(3) Psychic.

While making full allowance for the influence of the other two factors, I am convinced that in Graves's disease the psychic factor plays a very large part. Happy people do not get Graves's disease. "But who is happy?" you may retort. True it is that it would be hard to find anyone who during the past seven years had not been subjected to some kind of unpleasant emotional strain, whereas only a limited number developed this disease. But in cases both of fully developed Graves's disease and in the *formes frustes* the history of shock, strain or psychic conflict is generally pronounced, even though the medical man is not able to obtain it for some time. Matrimonial causes frequently lie at the root of the trouble, and these are not reasons which the patient cares to parade. The factor of shock was shown repeatedly during the air raids on London, as it was after the San Francisco earthquake and the Kischineff massacres. As Coné has expressed it, the emotions rather than the will affect structure. Now, the emotions find their expression through the sympathetic nervous system, and it is the sympathetic that innervates the thyroid gland. Cannon's classical experiment on cats definitely proved that stimulation of the cervical sympathetic would cause exophthalmic goitre. Once the vicious circle is started it is hard to break, for the sympathetic stimulates the thyroid and thyroid secretion lowers the threshold to sympathetic stimulation. To my mind, operation, radium or x rays, operate merely as factors in breaking this vicious circle by diminishing the amount of thyroid secretion and thus allowing the balance to be restored. But the earlier and more efficient the medical treatment the less frequently will surgical interference be required. And for medical treatment to be efficient all those factors must be carefully investigated, remembering that it is when more than one of them is at work that Graves's disease is most likely to result. Treatment will consist of rest, psychotherapy in the widest sense, elimination of toxic sedative effect upon the sympathetic. Indeed, this drug has been used in America as a test for hyperthyroidism. For while it is generally well tolerated in this condition, patients with an adenomatous or compensatory enlargement of the thyroid gland will display symptoms of cinchonism fairly soon. I usually give it in 5-grain doses three times a day for men and in 2½ to 3-grain doses to women.

THE INFLUENCE OF HYPERTHYROIDISM ON CARBOHYDRATE METABOLISM.

As is well known, glycosuria occasionally happens in hyperthyroidism, while lowering of carbohydrate tolerance is more common. What is not so clearly recognized is that the curve

sugar in the blood after ingestion of carbohydrate is, as far as my observation goes, always abnormal. Usually the amount of sugar in the blood rises to a level at which glycosuria would normally occur, yet without the appearance of any sugar in the urine. There is also a delay in its return to the normal level. Since glycosuria does not occur, it would appear as if the kidney threshold for sugar had risen, presumably as a compensatory mechanism. This rise in blood sugar is the method by which the thyroid secretion provides for the increased heat production in fever. In other words, both in Graves's disease and in fever the thyroid contributes towards increased katabolism by mobilizing sugar into the blood stream, and the kidney holds it there by raising the threshold against its excretion. It is noteworthy that in several of my cases of this type transitory glycosuria has nevertheless occurred under emotional stress, and amenable glycosuria has come on as the hyperthyroidism became less acute. I would interpret this by saying that the threshold was lowered again before the carbohydrate action passed off. Conversely, in myxoedema the level of the blood sugar remains low, even after the ingestion of considerable amounts. In part, no doubt, these effects of the thyroid are due to its antagonism to the pancreas, this antagonism is expressed not only (1) in the high blood sugar which is common to increased action of the thyroid and diminished action of the pancreas; and (2) in the mydriasis following instillation of adrenalin into the eye, which occurs under similar conditions; but also (3) in the output of pancreatic diastase in the urine, which is diminished in hyperthyroidism.

INTERMITTENT SWELLING OF THE THYROID IN CERTAIN NERVE STORMS.

The close association between the thyroid gland and the emotional nervous system is seen in the following three cases:

CASE I.

A lady of 50 was brought to see me because she suffered from periods of depression followed by periods of excitement, tachycardia, and tremors, in which the thyroid swelled. Hysterectomy had been performed four and a half years before, and a cystic leucoma had been removed from her thyroid ten years ago. She had no glycosuria after 100 grams of dextrose, and, unlike the ordinary case of hyperthyroidism, her urinary diastase was rather high. This was not observed, however, during a period of excitement. The effect of quinine hydrobromide was to take out the periods of excitement, but to leave the periods of depression as severe as ever. Careful search was made in this case for a toxic factor, without success.

CASE II.

A girl of 20 was admitted to hospital under my care with the story that some eight months previously her ovaries and tubes had been removed on account of tuberculous disease. After this she became distinctly fairer in complexion, and put on weight considerably. She suffered from hot flushes. Her thyroid had been rather full before the operation, but this had been less noticeable since, except during the attacks for which she was admitted to hospital. These occurred every three to four days. There was no aura, and consciousness was almost but not completely lost. She flushed and choked, while the pulse and respiration quickened very much. The attacks lasted about six minutes, and ended quickly, though the pulse rate subsided more slowly. The thyroid swelled noticeably in the attacks, and she passed a small amount of sugar then, but not at other times. Under iodine and opocaps of ovomammoid the attacks ceased completely—the last having occurred on September 4th. Her weight has fallen considerably, the hot flushes have ceased, and her general condition has greatly improved.

CASE III.

A man of 51, who had been subject to *petit mal* for three months following an accident thirteen years ago, had a recurrence of these attacks after another accident in 1917. In July, 1921, he had malaria, after which his *petit mal* assumed some new features; on recovering from a brief unconsciousness he became restless and excited, complained of difficulty in swallowing, and his thyroid swelled. On one occasion it was only the left lobe that enlarged. He is a man of great intelligence, and he expressed himself as feeling completely disorientated for about ten minutes by an attack. A curious feature was his bradycardia, the pulse rate varying from 48 to 52. Even when his temperature rose to 104° in an attack of malaria his pulse only went up to 64. Yet on vigorous exercise the pulse rate rose to 95 for a short time. I associate this bradycardia with his epilepsy.

It is interesting to note that the first two patients had their endocrine balance upset by the induction of an artificial climacteric, one in early life, the other shortly before the time when it would have normally occurred. I should like to call special attention to the benefit derived from the ovomammoid extract in apparently restoring endocrine

balance in the second case. In the third case no doubt the thyroid specially suffered in the outbreak of excitement because it was already irritated by an infection—namely, malaria. I have since heard that on quinine hydrobromide till free from malarial parasites, and then on potassium bromide, he has kept entirely free from attacks. I also learned he had nutritional troubles, which, as I have said, so often have an effect on the thyroid gland. The absence of tachycardia with emotional excitement suggests that tonic played a part in this case. But all three cases illustrate the influence of emotional excitement on the thyroid.

Such cases should, I think, be distinguished from the condition of thyroid instability described by Leopold-Levi and Rothschild where there are spurts of hyperthyroidism occurring with a background of continuing hypothyroidism. This may be compared to a state of "irritable weakness." In one such case I saw these spurts were accompanied by tachycardia and tremors, yet her weight was increasing, and until small doses of thyroid extract given she appeared to be developing acute myxoedema. Pituitary extract was first tried without benefit, but thyroid the condition cleared up rapidly.

It may well be asked what are the points which guide us in determining whether thyroid enlargement is compensatory for a deficiency of thyroid secretion, or whether there is genuine hyperthyroidism. I would say that if metabolism is increased, if there is wasting, pyrexia, continued tachycardia and tremors, with attacks of diarrhoea and if there is any glycosuria, the case is certainly one of hyperthyroidism, and thyroid extract should not be given, but quinine hydrobromide is indicated. If these signs are lacking and the patient is putting on weight, thyroid extract should be given a trial.

THE CARDIO-VASCULAR COMPLICATIONS OF THYROID DISEASE.

Hypothyroidism.

(a) *Vascular*.—The liability of the subjects of hypothyroidism to chilblains is well known. A condition Raynaud's disease is not uncommon. It will usually found that there is then a well-marked intestinal toxæmia usually the result of definite viscerosptosis, which exhausts the thyroid while also affecting the vessels. Morley Roberts has suggested to me that histamine is the product of putrefaction which damages the capillaries and from some preliminary investigations I have made seems to me this may be the case. Treatment should be directed to the condition of the bowel, such as by a Colonic support, Plombières douches and intestinal antiseptics.

(b) *Cardiac*.—I have seen a number of instances in patients with hypothyroidism and feeble flabby hearts which have been labelled as suffering from "fatty heart." I agree with Leopold-Levi and Rothschild that thyroid extract benefits such cases greatly, but that great care is required in dosage. Naturally some apprehension may be felt in giving such a drug in this condition, but half a grain a day has never, in my experience, produced any unpleasant symptoms.

Hyperthyroidism.

(a) *Vascular*.—Goodall and Rogers describe three stages in the reaction of the blood pressure to Graves's disease. First, a preliminary rise from the sympathetic irritation which has caused the thyroid enlargement, possibly simultaneous stimulation of the adrenals. Next, a fall in pressure from the vaso-dilator effect of the excessive thyroid secretion, which they regard as the safest stage for operation. Thirdly, a rise due to reduction of this secretion, accompanied by some change such as cardiac hypertrophy.

(b) *Cardiac*.—Here again we are indebted to Goodall for a clear exposition of the position. Prolonged tachycardia may exhaust the myocardium. This leads to atony, dilatation with valvular incompetence. Then myocardial degeneration is apt to result, which may go on to arrhythmia and fibrillation. Quite lately I have seen three instances of this in the later stages of Graves's disease. Further, there is a danger of this fibrillation affecting the ventricle after operation, which is probably the cause of the sudden death which sometimes follows it, as unfortunately happened lately in a case under my care. There is a liability to considerable rise of blood pressure after operation, which greatly adds to the work of an already overtaxed heart. Ventricular fibrillation is not compatible with life.

THE PARATHYROID.

These glands were first described as distinct entities by Sandström, while Gléy was the first to attribute to them functions apart from the thyroid. But in 1907 Forsyth concluded that they were merely portions of the main thyroid gland which had not yet formed vesicles, and that all the intermediate stages between thyroid and parathyroid tissues occurred. Berry, as the result of 1,338 operations for the removal of goitre without the occurrence of tetany, altogether discredited any separate function for the parathyroids; but as he states he always leaves a piece of gland at the hilus, he presumably does not completely remove them. The consensus of opinion at the present time seems to be that the general effect of the parathyroids on metabolism is antagonistic to the thyroid, and that they play a special part in the fixation of calcium in the tissues. If the nervous system lacks calcium it becomes more irritable, and tetany is likely to occur. It is possible, however, as pointed out by Noël Paton, that it is the accumulation of methyl-guanidine which occurs after parathyroid removal that causes tetany, since injection of this substance will produce a similar effect. Parathyroid secretion may distoxidate methyl-guanidine. Korenechevsky has repeatedly produced tetany in rats by destroying their parathyroid tissue, which forms a distinct encapsulated structure in these animals, with the electric cautery. Clinical observations by Hurst, Cordier, and G. H. Clarke support the view that parathyroid disease causes tetany, tremors, and fibrillary twitchings, among other symptoms, which can be relieved by administration of parathyroid extract. That these glands have some effect in checking calcium loss has been shown by comparing the output of calcium salts on thyroid and parathyroid extract. Quite recently Vines has shown the value of parathyroid extract in promoting the healing of ulcers of the skin and stomach. He suggests that various chronic infections damage the parathyroids and thus prevent healing by diminishing the amount of ionizable calcium salts in the blood. Walter Edmunds has noted that after parathyroidectomy animals may be kept alive longer by an exclusive milk diet, with the addition of calcium lactate. He also quotes Eppinger, Falta, and Rudinger, who found that the removal of the parathyroids, one by one, tended more and more to favour the onset of glycosuria. This would suggest that the parathyroids work with the pancreas and fall into the anabolic group, while antagonizing the thyroid, which belongs to the katabolic group. It also raises the question as to whether the increased calcium loss in diabetes may be due to parathyroid deficiency.

CONCLUSION.

We are thus led to the conclusion that the position of the thyroid gland in the endocrine system is that of a powerful activator of metabolism. In this respect it co-operates with the adrenals and pituitary, and antagonizes the pancreas and parathyroids. On the nervous side it co-operates with the sympathetic nervous system, both being stimulated to increased activity by it and lowering the threshold to it. In this way it plays an important part both in external and internal defence. Externally it leads to greater manifestation of energy in the direction of fight or flight; internally it quickens the reactions to bacterial invasion. An important way in which it accomplishes this is by mobilizing the blood sugar. This increased supply of sugar may either be used for muscular energy in external defence or for heat in the febrile reaction of internal defence. As a provision against waste of this sugar the kidney threshold is raised to prevent its escape into the urine, so that despite hyperglycaemia there may be no glycosuria. Yet this blood sugar may exceed even this raised threshold, so that some escapes. This is particularly likely to occur during emotional excitement, when the gland is apt to enlarge. It interacts also with the gonads, and the undoubted fact that it plays a more active part in female metabolism may be due to its origin from the uterine of a Palaeozoic ancestor. This interaction may account for the disturbances which are so apt to occur in the gland after an artificial or natural climacteric. That in the former instance this is likely to take the form of intermittent hyperthyroidism may be due to the gland being still in full activity; in the latter instance hypothyroidism is more common, presumably because the gland is already undergoing retrogression. The combination of a distressing emotion of matrimonial origin with a toxæmia of alimentary origin is the most fertile cause of hyperthyroidism, and the biological consideration here presented may help to explain why this is the case.

RHEUMATOID ARTHRITIS DUE TO INFECTION
OF THE NASAL ACCESSORY SINUS.*

BY

P. WATSON-WILLIAMS, M.D.LOND.,

LECTURER ON OTOTOLOGY, RHINOLOGY AND LARYNGOLOGY, UNIVERSITY OF
BRISTOL; SURGEON FOR EAR, NOSE, AND THROAT DISEASES,
BRISTOL ROYAL INFIRMARY.

IN this ancient city of Bath which our medical colleagues have made renowned throughout the world, not as the Mecca of the rheumatic, for that it has been long before medical practice could be termed a science, but as a centre where exceptional clinical opportunity has been utilized for scientific research and post-graduate study, it is with a certain sense of diffidence that I chose for the subject of my address such a group of diseases as rheumatism, neuritis, and arthritis.

The recognition of the infective nature of a considerable percentage of clinical syndromes loosely designated rheumatism, rheumatoid arthritis, chronic articular fibrositis, neuritis, and so forth, has led to investigations directed to the many possible sources of such infection. While the teeth, gastro-intestinal and genito-urinary tracts have received due consideration, there lies in the nasal accessory sinuses a possible source of chronic systemic infection which merits more attention than has hitherto been accorded to this region. And if, as I hope to show, the nasal sinuses may contain the cause even in a percentage only of such intractable diseases, it is the more important that these nasal cases should be recognized inasmuch as it is relatively easy to determine the presence or absence of nasal sinus infection.

Why a nasal source of the infection in rheumatoid arthritis is so liable to escape attention, and how it is that the joint affection is more prone to arise in patients whose nasal symptoms are slight rather than in cases where there is profuse purulent rhinitis, I shall endeavour to explain below. Before doing so I submit brief notes of some cases which have benefited so definitely by treating the infection of the nasal sinus that it seems to leave no room for doubt that by such treatment the source of the joint disease was eliminated. Of three examples the first illustrates the earlier or slighter forms of articular fibrositis; the other two were typical cases of chronic rheumatoid arthritis (fibrositis) of long standing.

CASE I.

Miss E. R., aged 40, was referred by Dr. Mary Morris, of Bath, on account of chronic fibrositis, involving several finger-joints, gradually developing for two years, chronic rheumatic pains in the legs and feet, central frontal headaches, and an occasional subjective sense of foul odour. For four years she had noticed some post-nasal catarrh, and this led her medical attendant to suspect a nasal source, particularly as treatment for pyorrhoea had failed to relieve her. Furthermore, the patient, formerly of a bright and active disposition, was mentally repressed. Examination of the nose revealed no nasal discharge whatever, yet the history of post-nasal catarrh and the general condition of the patient was so suggestive of a latent infection of an accessory nasal sinus that exploration of the sinuses seemed warranted if only to eliminate such a source of infection as a cause of the serious disease that menaced her health. Exploration of the maxillary antrum, sphenoidal sinuses, and the left posterior ethmoid cells was made by means of my suction syringe, so as to obtain a "deep-sea fishing" from each cavity. No pus was obtained, though the left antrum and the left posterior ethmoid cell yielded turbid contents. On bacteriological examination by Dr. Kay Monatt, both the maxillary antrum yielded cultures of *Staphylococcus pyogenes aureus*, and the left ethmoidal cell staphylococcus, together with a bacillus that "is frequent in influenza-like catarrhs"; the other sinuses were uninfected. A solution of 1 in 10,000 mercury biniodide was injected into each cavity, and the diseased antrum was opened and drained. The patient rapidly improved and was further benefited by antigenic vaccines from the cultures. Not only did the rheumatic swellings largely resolve, but the general health improved and she regained her former cheerful disposition and betook herself actively to games.

The second example is of interest, not only on account of the very long history of the joint affection, but also as being one of the very large percentage of cases of appendicitis occurring in association with chronic infective rhinitis.

CASE II.

Miss B. D., aged 46, had suffered from rheumatism in the left knee from the age of 14 and in the right from one year later. This condition persisted without much change till, sixteen years later, the left wrist and finger-joints became involved; not very long afterwards she had an attack of neuritis in the left shoulder. Ten years before I saw her she began to suffer from pains and stiffness

* Abstract of the Presidential Address to the Bath and Bristol Branch of the British Medical Association.

in both ankles and the right wrist as well as the left. She had undergone five courses of baths at Bath in different years and for three years had been treated at Vittel. In 1905 her appendix was removed.

She had had some nasal trouble on and off since 1881 when she first consulted the late Dr. Edward Woakes, and at varying intervals she had consulted three other rhinologists for nasal trouble.

On examination of the nasal passages there was little to be seen beyond some strings of opaque-cent tenacious mucous discharge, unseen except by endorhinoscopy. Cultures of the contents of the sinuses obtained by exploratory lavage were made by Professor Walker Hall, who reported that the maxillary antral cavities were sterile, but that the sphenoidal sinuses yielded *Staphylococcus aureus* and *Streptococcus ferriis*. Fuller details of the case, particularly with reference to the pathological investigation, are given in a report to the Royal Society of Medicine. The sinuses were disinfected by injecting colloidal argenticum and great improvement followed, particularly when later the infected sphenoidal sinuses were opened and drained. She lost all her headaches and her stiff joints became more supple and free from pain, but the most striking feature was the very marked diminution of the chronic rheumatoid arthritis, swelling of the wrist, and the absence of pain. An improvement which had been maintained when I saw her a year later.

CASE III.

W. R., a man aged 54, had well-marked typical fibrositis in the left wrist and finger-joints of three years' duration; this had been followed by similar involvement of the right wrist and finger-joints, the knee-joints and one ankle. He had been through a course of baths and massage, first at Buxton and a year later at Bath; he was considerably relieved of the joint pains for the time being on each occasion. The patient had chronic catarrh, deafness, and slight rhinitis, and was mentally depressed. The successful result obtained in the previous case led me to explore this patient's nasal sinuses. The left maxillary antrum was found to contain much thick pus, the right was clear. The right sphenoidal sinus yielded a heavy growth of *Staphylococcus albus*. The sinuses were washed out and disinfected, and all the joints and swellings and pains were strikingly improved; after opening and draining the involved sinuses all the old pains had gone, and the stiffness and swellings of the joints abated.

In the course of a discussion following the contribution I made on this subject in the Laryngological Section of the Royal Society of Medicine several speakers cited examples occurring in their own practice. Mr. O'Malley, for instance, referred to a man, aged 50, with orbital cellulitis and a history of rheumatoid arthritis for twenty-five years; he opened the ethmoid region, evacuating foul-smelling pus, and eighteen months later the patient came again, saying, "The extraordinary thing is that I have no aches and pains in my joints now, whereas previously they had ached for years and years." At the same discussion Colonel Sharp cited an instance of fleeting rheumatic pains and well-developed melancholia in a woman. Many forms of treatment were tried in vain by her physician, and she was referred to Colonel Sharp to examine her tonsils, in the hope that something might be found to account for the rheumatism. But the tonsils and nose were healthy, except that the left sphenoidal sinus contained slightly milky fluid. The sinus was opened and drained, and within three days the melancholic regained her usual cheerful disposition, and in ten days she left, quite free of rheumatic pains—a good result which continued up to the time of the report several years afterwards. It is difficult to avoid the conclusion that in this patient the melancholia, as well as the meniscular rheumatism, was directly due to toxic infection from the left sphenoidal sinus, and it is noteworthy that, so mild apparently was the sinus infection, that there were no localizing symptoms, the infective source being discovered here almost accidentally. A well-marked example of melancholia attonita due to nasal sinus infection was seen by me, in consultation with Dr. Wilson Smith, about two years ago.

CASE IV.

A lady, aged 57, had suffered from purulent nasal discharge for about seven months, associated with headache and increasing loss of memory and mental depression, culminating in a state of mental stupor. Dr. Wilson Smith suspected that the nasal disease caused the mental condition, and examination of the nose revealed polypoid degeneration in the right middle meatus, with pus coming from the right frontal sinus and the right maxillary antrum. These sinuses were opened and drained. The pus from the right antrum yielded staphylococci, with a few streptococci; the left antrum and sphenoidal sinuses were apparently sterile. Several Jaccard teeth were subsequently removed. There was no great mental improvement for nearly a month; then her mind began to clear and two months after the operation she was almost herself again mentally.

Many instances of profound mental depression, and in not a few suicidal impulses, have occurred among my cases of nasal sinus infection, but I think the examples I have cited

are sufficient to emphasize the profound, and sometimes disastrous, effect on the central nervous system of a toxic infection from the nose.

To explain the relation of the general systemic manifestations to a source of infection in the nasal sinuses, I may digress for one moment to take the simplest and probably most common of all sources of toxic systemic infection, that due to enlarged tonsils and adenoids, so commonplace that the lessons such cases afford are apt to escape attention. A typical patient suffering from diseased tonsils and adenoids is listless, apathetic, with so-called poor circulation, and recurring nasal catarrh. With the removal of the septic adenoid masses of the nasopharyngeal and faucial tonsils the whole picture is changed and the transformation from a listless, apathetic, anaemic child with poor circulation is only to be accounted for by the removal of the sources of a persistent septic infection. One of the most striking facts about these cases is that often enough it is in those children in whom the tonsils and adenoids are relatively small that the greatest benefit results, and that in others where the hypertrophy is great the general symptoms are comparatively slight. We cannot say that the larger the tonsils and adenoids the more pronounced are the evil effects resulting from their presence; we are driven to the conclusion that the aggregations of lymphoid follicles called tonsils are in fact protective up to a point, and that when the hypertrophy proceeds *pari passu* with their ingestion of the infecting organisms the balance is largely held and the septic absorption inhibited until the tonsils have become overwhelmed by the infecting organisms.

When we turn to a consideration of nasal catarrh as a source of systemic infection we are confronted with a similar paradox. It will often be found that a patient whose nose is full of polypus and constantly streaming pus from one or both nostrils, looks bright, ruddy, and robust, and even fat, whereas another patient, who has nothing but a slight non-purulent nasal discharge, is depressed, thin, and sallow, and obviously in very poor health. I think the explanation is that, given an infection when there is a profuse outpouring of polymorphonuclear cells with phagocytosis, the invading organisms are so largely inhibited or ingested that the patient is protected from toxic absorption, whereas in other cases, where a similar infection exists with but a few pus cells, toxic absorption is more pronounced. We see precisely analogous conditions in post-mortem wound infection: if the point of infection forms an acute abscess it is usually a local inconvenience, but if the infection spreads up the lymphatics there is infinitely greater danger of acute general septicæmia. It is necessary to emphasize the fact that the slightest and apparently harmless nasal discharges may be clinically more virulent and more prone to cause systemic infection than the profusely purulent discharge, otherwise we may fall into the error of arguing that, because with definite purulent discharges from the nose systemic infection is unusual, it must follow that with the less marked nasal trouble the nasal origin of an infection must be even a more remote contingency. This very natural error leads us to overlook the possible import of a slight nasal or post-nasal catarrh, particularly as a patient suffering from a painful affection, or who is feeling decidedly ill, does not pay much attention to such a trivial complaint in his nose or throat. No class of case serves better to support this view than the result of toxic infection of the optic nerves from nasal sinusitis, because in the ocular manifestations we can to some extent measure the damage done by the poisoning and the benefit following the removal of the source of infection by opening and draining the involved and infected nasal sinuses.

If we take one of the simplest examples of a canalicular neuritis due to sphenoidal sinus suppuration we observe that the optic nerve sheath lies in close contact with the very thin upper part of the outer wall of the sphenoidal sinus, forming sometimes a bulging prominence in the sinus wall, sometimes running in a thin bony canal through the cavity of the sinus. But the usual result is that toxic absorption through the thin sinus wall involves first the inner aspect of the optic nerve sheath, and consequently the inner fibres of the optic nerve are the first to suffer, with resulting contraction of the temporal visual field. The contraction of the visual field may be considerable before the central visual acuity is affected, and if the involved sinus is opened and drained there is good prospect of recovery of vision and of the visual field expanding to normal.

A CASE OF DIAPHRAGMATIC HERNIA.

[With Special Plate.]

BY

GEORGE J. LANGLEY, M.D., M.R.C.P.,

PHYSICIAN ANCOATS HOSPITAL, MANCHESTER.

With Surgical Notes by JOHN MORLEY, CH.M., F.R.C.S.,
and Radiological Notes by J. M. WOODBURN MORISON,
M.B., C.M., of the same Hospital.

A LARGE number of these cases are now on record, but they still rank as pathological curiosities. They may be divided into several groups, which are very distinct:

- (a) Traumatic cases, of which the war has provided a regrettably large number.
- (b) True diaphragmatic hernia arising from a congenital defect in the diaphragm, through which abdominal content herniates.
- (c) Eventration, in which there appears to be a congenital weakness of the diaphragm and consequent dislocation of related abdominal viscera.

The following case illustrates the difficulties of accurate diagnosis and of selecting the best method of treatment.

A schoolgirl, aged 10 years, was brought to hospital, having had a cough and cold for two weeks. There were eight other children in the family, all healthy and well. The mother had had one miscarriage, and one child had died at the age of 12 months from zymotic enteritis.

The patient had never been robust, but the only serious illness occurred when, at 2½ years of age, she developed morbilli followed by pneumonia. The child had been to hospital on three or more previous occasions for trivial ailments, but in spite of this had lost very little time from school. The only present complaint was of cough and cold. At no time had there been any reason to suppose that the gastro-intestinal tract was other than normal.

Routine examination resulted as follows:

The child is small and thin, with normal colour and no deformities. The chest is poorly covered, the ribs being easily visible and respiratory movement normal. The area of cardiac dullness, position of apex beat, and heart sounds were normal, and no extension of dullness to the right was found. The pulse was good.

The right lung appeared healthy, but on the left side an area of dullness to percussion was found, extending downwards from the fifth rib in the nipple line, eighth space in the anterior axillary line, and angle of the scapula behind. Over this area vocal resonance and fremitus were almost absent, while breath sounds were diminished but normal in character, with no adventitious sounds. In the abdomen the liver dullness extended from the sixth rib to the costal margin, where its edge could be felt; the spleen could also be felt, its dullness being merged in that above described.

No other abnormality was found beyond the fact that the pupils, though fully active, were not quite equal, the left being slightly larger than the right.

While under observation it was found that the upper limit of percussion dullness over the left lung was variable, being sometimes a rib or space lower than that above described. Hippocratic succussion and the coin sound could sometimes be obtained. At no time during observation were there any symptoms pointing to the digestive tract.

Dr. Morison, radiologist to the hospital, made repeated examinations of the chest at all stages of digestion, and the following is a condensed report of his findings:

The screen examination of the chest showed a complete regular dome on the left side, extending as high as the level of the third rib in front, and enclosing an air space through which in the upper part lung tissue was seen. At the bottom of this air space there was a sharply defined horizontal line of fluid on which waves and ripples were produced by palpation of the abdomen.

No definite movements of the bow line in the chest were observed during respiration, although on one occasion I thought there was a slight reversed movement (an upward movement during inspiration and a downward during expiration), but I was not quite confident of this.

The dome of the right diaphragm was at the level of the tenth dorsal vertebra. Its movements were normal. The heart was slightly displaced to the right. There was an increased density of the root shadows of both lungs.

On giving a bismuth meal the food was held up at the cardiac opening of the oesophagus, the lower third of which was dilated, the obstruction was soon overcome, and the stomach was seen to fill in an irregular manner. The cause of this was apparent when the patient, who up to this stage had been examined in the postero-anterior position, was placed in the right anterior oblique position. There were two sacs, the shadows overlapping in the postero-anterior position. The upper sac, when filled, spilled in a forward direction into the lower. The pyloric end of the stomach

was directed backwards, and was not well formed. There was no delay in emptying.

In the lying-down position the bismuth meal passed up to the top of the bow line in the chest, displacing the air, and completely filling the dome, which was not altered in position. Nothing abnormal was detected in the small intestine. The colon was well outlined, and the splenic flexure was found to rise alongside the air cap of the stomach to the top of the bow line in the chest, but not beyond it. At other times the whole of the dome in the chest was filled by the air cap of the stomach.

A barium enema confirmed these observations on the colon, which was otherwise normal.

It soon became apparent that in this case the determining factor was the x-ray finding, and that it was the only possible means of differentiating the genuine hernia from an eventration.

The difficulty in the case largely lay in the fact that the patient had come under observation in the absence of symptoms, whereas so many of the other recorded cases had been acutely ill or had shown active gastric symptoms.

It was finally determined that the case was most probably one of true congenital diaphragmatic hernia, and that these cases usually did not come under observation until some acute condition, as volvulus or strangulation, had occurred. The prognosis was then extremely bad, and it was decided that for these reasons it were wiser to operate under quiet conditions and so prevent the onset of these more serious symptoms.

Mr. John Morley, surgeon to the hospital, was therefore asked to see the case, and operation was undertaken. It had been previously determined that the function of the stomach as regards acid and pepsin was normal, or at least that part of it from which the test meal was recovered.

Operation took place on February 19th, 1920; gas and oxygen with ether were administered by Dr. K. B. Pinson.

It was decided to perform thoracotomy in the first place, as it was considered that this would facilitate reduction of the herniated viscera through the diaphragm by affording more direct access. Accordingly, with the patient in the right lateral position, an incision five inches long was made along the eighth left rib, with its centre in the posterior axillary line. The rib was resected to the extent of four inches and the pleura opened. The ribs above and below were retracted widely by Tuffier's rib spreader.

The fundus of the stomach could now be seen projecting up into the thorax far above the level of the incision. It was at once apparent that a transparent layer of thinned-out diaphragm formed a covering for the elevated abdominal viscera and separated them completely from the true pleural cavity, which was greatly reduced in size. To the highest point of this thin translucent diaphragm the base of the left lung was firmly adherent. These adhesions were fibrous and vascular and were readily divided. The diaphragmatic sac was now incised. On opening it the splenic flexure of the colon and left extremity of the great omentum and greater curvature of the stomach were presented. These were quite free from adhesions. The upper pole of the spleen also came into view.

It was now plain that there was no functioning diaphragmatic muscle at all, but that the whole diaphragm was merely represented by a thin sheet consisting of pleura above and peritoneum below, with some rather dense fibrous tissue between. A partial excision of this diaphragmatic sac was determined upon, with the object of bringing down its level as near to the normal as possible, and so reducing the distortion of the stomach and allowing more expansion of the lung.

The opening in the sac, therefore, was enlarged backwards with scissors towards the posterior aspect of the heart, and an elliptical strip of thinned-out diaphragm removed. The abdominal viscera were now packed downwards, so as to remove upward pressure on the sac, and the rent in the sac was sutured with two layers of catgut in such a manner as to overlap the edges broadly and so reduce the diaphragmatic level. When this was completed the dome of the diaphragm reached to the seventh rib in the mid-axillary line. After wiping blood clots from the pleura the rib spreader was removed and the pleura and intercostal muscles sutured with continuous catgut. The superficial muscles and the skin were then sutured in layers.

The patient took the anaesthetic well, but the pulse became very rapid during the suturing of the diaphragm and reached a maximum of 180.

Convalescence was uneventful and rapid. There was considerable pain on respiration for the first few days, but it was noticeable that no pain was felt at the usual site of referred pain from the phrenic nerve—the tip of the left shoulder.

Microscopical sections of the piece of diaphragm removed showed normal endothelium on the pleural and peritoneal surfaces, and between these dense fibrous tissue, with no sign of muscle fibres. No nerve fibres could be made out in sections that were specially stained to show them.

The subject of non-traumatic hernia of the diaphragm was discussed by Scudder in 1912, who stated that up to that date 1,000 cases had been reported, most of which were discovered *post mortem*; 53 operations had been performed, of which 11 were thoracotomies, with 7 recoveries and 4 deaths, and 42 were explored by an abdominal incision.

with 7 recoveries and 35 deaths. The diagnosis was made beforehand in only six cases. Operation was usually performed for acute intestinal obstruction.

Giffin, writing in 1912, and discussing the differential diagnosis between congenital hernia of the diaphragm (with prolapse of viscera through a gap in the diaphragm) and congenital elevation or evagination of the diaphragm, enumerates certain skiagraphic features which, he considers, help to differentiate the two conditions.

Giffin considers that: (1) A dome-shaped outline of the diaphragm is invariable in congenital elevation, whereas the shadow of the diaphragm may be irregular in hernia. (2) Mottled lung tissue may be seen through the clear area in the thorax in cases of hernia, but not in cases of elevation. (3) If the colon be found extending up into the chest and beyond the bow line, the case is one of true hernia. (4) Paradoxical respiratory displacement in which the affected side, usually the left, moves up on inspiration and down on expiration, is found usually in hernia. In congenital elevation the movements of the diaphragm are normal, though of reduced range.

Our study of the present case would appear to disprove much of this. Thus we found that mottled lung tissue could be seen through the clear area below the dome formed by the shadow of the diaphragm; the splenic flexure of the colon projected high up into the thorax, and although reversed diaphragmatic movement was doubtful before operation, yet it became well marked after the operation, and this although the diaphragmatic bow line was at a lower level.

The recognized nomenclature of these conditions is hardly satisfactory. Custom has decreed that cases of congenital defect or gap in the diaphragm, with prolapse of viscera into the pleural cavity through that gap, should be labelled "hernia," although the hernia possesses no sac; whereas to cases such as the one we now report, in which the thinned out diaphragm forms a veritable sac, the term "hernia" is denied. It must be admitted, however, that to alter the terminology now would be to lead to considerable confusion.

The etiology of congenital elevation of the diaphragm remains obscure. The appearance of our histological preparations suggests that the intermediate fibrous tissue was essentially degenerated and fibrosed muscle, and this would suggest a congenital absence or lesion of the left phrenic nerve, and in this connexion the inequality of the pupils is interesting. But this does not carry us very far, since we are without a clue as to the cause of the nerve lesion.

The condition cannot be ascribed to a failure in the descent of the diaphragm, since the skeletal attachments of that muscle at its periphery were found to be perfectly normal, and its great elevation was plainly due to its intrinsic weakness and inability to withstand the upward thrust of the abdominal viscera.

A further radiological examination in this case, four weeks after the operation, showed that the collapsed lung had completely expanded. There was considerable thickening of the shadow cast by the bow line in the chest, and now paradoxical movements of the diaphragm were seen, the bow line in the chest descending during expiration and ascending during inspiration, while the movements on the right side were normal. The examination of the stomach now showed that the two sacs were no longer present. Three months later examination showed that adhesions were beginning to form, the movements of the bow line in the chest being now greatly restricted though still reversed.

Conclusions.

It would appear from this case that:

(a) Physical signs at the base of the left chest may be sufficiently well marked in diaphragmatic hernia to make the differential diagnosis from subphrenic abscess and pyopneumothorax a matter of considerable difficulty.

(b) Ultimate diagnosis must remain in the hands of the radiologist, but the points which have in the past been regarded as valuable in differentiating true hernia from evagination cannot be entirely relied upon.

(c) In the light of recorded cases and the ultimate acute abdominal condition which may, and probably will, supervene, exploration is desirable in these cases, unless it can be conclusively proved that the case is one of simple evagination.

HEREDITARY POLYDACTYLISM.

[With Special Plate.]

BY

ROY F. YOUNG, B.A., M.B., B.Ch.

ASSISTANT SURGEON, WESTERN INFIRMARY, GLASGOW.

The following case of bilateral double great toe presents some points of interest, more particularly from the operative point of view.

The genealogical table is very incomplete, and can only be traced to the grandfather of this patient. Prior to him it is reported that accessory toes have "descended down, but was a matter which was never discussed." The only deformity has been that of additional toes.

With regard to the pathology, the x-ray appearance (see plate) confirms the opinion that the accessory digits are due to fission. On the right foot the proximal phalanges were fused for half their length; there is also incomplete fission of the metatarsal. On the left foot the separation of the phalanges was complete; the x-ray appearance also suggests that the more external or lateral toe is the more rudimentary.

Operation.

After due consideration it was decided to remove the medial toe on the right foot and the lateral toe on the left. The reasons for the latter choice were the distinctly more rudimentary nature of the lateral toe on the left foot, and that the resulting scar would be less liable to pressure from the boot. On the other hand, by removal of the medial toe better alignment could be secured. Further, it was of value to discover which method gave the more satisfactory result.

The result was very convincing. The patient was seen two months after operation. The right foot was completely satisfactory in use and appearance, and there was no irritation from the scar. The left foot was found much as before operation. Three months later the left foot had improved considerably, both in use and in appearance, but at the end of a day's work it felt very tired. A year after operation the left foot was still less satisfactory than the right.

I have to express my thanks to Dr. Duncan Macartney, in whose ward I treated this case.

THE CARELLI METHOD OF PERIRENAL INFLATION.

AN ACCOUNT OF A RECENT DEMONSTRATION AT THE FRENCH HOSPITAL.

[With Special Plate.]

BY

F. HERNIMAN-JOHNSON, M.D.

DIRECTOR OF THE X-RAY AND ELECTRICAL SERVICE, THE FRENCH HOSPITAL, LONDON; PHYSICIAN, X-RAY DEPARTMENT, THE MARGARET STREET HOSPITAL FOR CONSUMPTION.

A short time ago Dr. F. G. Crookshank, physician to the French Hospital, while visiting Paris, was taken by Dr. Andre Leri to see a demonstration on pneumoperitoneum and the inflation of certain tissues, by Dr. Carelli of Buenos Aires. He was greatly impressed by the beautiful examples shown of gall-bladder disease, adhesions, cystic ovaries, Fallopian tube disease, and of pregnancy diagnosed at one month owing to the small but uniform increase in size of the uterus being made visible. What struck him most, however, was the entirely new procedure of perirenal inflation, an idea the carrying out of which is due to Dr. Carelli.

Dr. Carelli has demonstrated his methods in Berlin and Vienna, and is about to do so in the United States. Dr. Crookshank urged him to visit London, and he consented, though at considerable personal inconvenience. It was arranged that he should give an account of his method at the Royal Society of Medicine, and I was asked to place my department at his disposal for an actual demonstration of

his kidney technique upon a patient. This I was most pleased to do. Dr. Carelli came to the French Hospital on December 8th, 1921, and, in the presence of several radiologists, performed a perirenal inflation.

The apparatus has been described elsewhere, as also the method: all I need do here, beyond referring very briefly to the principles involved, is to give some personal impressions.

By ordinary radiography the lower half of the kidney can be shown, provided that the patient is well prepared. Under favourable circumstances, the whole organ may be distinguished, but the outline is often vague and difficult to differentiate from the surrounding parts; this is more especially the case when disease, such as tuberculosis or malignancy, is present. Nor can one by the usual methods demonstrate the suprarenal capsule. On the other hand, the injection of gas into the peritoneal cavity does not fully define the outline, as the kidney is an extraperitoneal organ. Dr. Carelli therefore resorted to the production of an artificial emphysema around the kidney itself, and he informed us that he had carried this out several hundred times without accident of any kind.

Unfortunately there did not happen to be in the hospital at the moment any cases suitable from a medical point of view, so that the hope of demonstrating some actual pathological condition had reluctantly to be abandoned. However, with some difficulty I induced a normal subject to submit to the procedure.

Method of Procedure.

The subject was made to lie face downwards on the x-ray couch, and Dr. Carelli first took steps to find the transverse process of the second lumbar vertebra. This he did (1) by tracing the last rib to its junction with the spine and taking a point 2 cm. below the angle and an equal distance from the middle line (the 2 cm. is of course an average measurement only); (2) by counting the spinous processes upwards from the fourth lumbar and taking a point midway between the second and first, as giving the required level.

The patient was a man of average build, weighing 11 st., and his bony landmarks were not difficult to feel; but Dr. Carelli explained that, in the case of a stout man, it is necessary to localize the process according to some of the well known methods used in the case of foreign bodies.

The site of the second transverse process having been ascertained, the skin was swabbed with iodine, and a fine platinum needle about 10 cm. long was pushed in vertically until brought to a stop against the bone. This is landmark number one. Up to this point the patient felt nothing other than the prick of the needle. Having called our attention to the fact that the needle was actually against the process, Dr. Carelli proceeded to alter the direction of the thrust—the point slightly forward and a little outwards, so that it slipped past the obstruction. He pushed the needle in until he believed that he had reached the perinephric areolar tissue. (The needle appeared to be buried to the extent of about 6 cm.) He then waited a moment to see if any blood came out through the needle. Had this occurred, it would have meant that a vessel was punctured, and a reinsertion would have been necessary. This is point number two. Having satisfied himself as to this, he next connected the needle with the manometer of the oxygen container. The latter is similar to the apparatus used for artificial pneumothorax, and need not be described. The manometer readings constitute a third, and a very important, point in the technique. As soon as the connexion was made one saw the column of fluid move up with inspiration, down with expiration—the opposite to what would have happened had the needle been in the pleural cavity. It appears that sometimes the manometer column does not move even though the needle point is in the perirenal space. If no movement occurs, and the needle seems to be at a proper depth, a few centimetres of gas should be very carefully introduced, when the manometer will give the usual indications. Should the needle point be in the muscle, pain will be produced at once, and the occurrence of pain (other than a dull ache) is always an indication that a retrial must be made.

Having pointed out these facts to us, Dr. Carelli closed the manometer connexion and opened the stopcock connecting the needle with the oxygen chamber. He then proceeded to inject the gas very slowly. The patient complained of an increasing ache in his loin, and asked for the injection to cease after it had reached about 500 cm. Dr. Carelli said this was sufficient in most cases; he stopped the pump and pulled out the needle. The latter is of such fine bore that the track closes immediately.

Dr. Carelli's usual procedure is then to turn the patient on to his back and take plates from above with some degree of compression. I asked if we might first screen, and we did so. The kidney, like an island in a lake of air, was plainly seen by all, and any gross changes in its size and outline could have been readily seen. A plate was then taken in this position—that is, tube below, patient on face.

The patient was now asked to turn over, and did so without much apparent discomfort. A plate was taken with the tube above, the patient on his back; he did not object to a moderate amount of compression. He got off the x-ray couch unaided, and Dr. Carelli made him bend his back in various directions to show that the remaining discomfort was slight.

The patient walked up some steps and along a corridor to a waiting taxi, and I took him to my rooms, as I wished to secure some radiographs with my own apparatus. A preliminary screen

examination, one hour after the original injection, showed no apparent diminution in the inflated area. Oxygen had been used, as it was the only gas available. Dr. Carelli himself always uses CO₂ because it is absorbed within an hour. But for the beginner oxygen presents certain advantages.

To sum up my personal impressions:

The essential points of the technique are—(1) Use of a fine needle; (2) accurate location of the transverse process of the second lumbar vertebra; (3) proper direction of the needle after it has struck the process; (4) use of needle open so long as it is being advanced: this permits observations of punctured blood vessels; (5) sound judgement as to depth of insertion; (6) determination of entrance of needle point into perirenal tissue by manometer readings; (7) slow injection of gas; (8) quantity not to exceed 500 cm.

As to indications for use, any case in which there are signs or symptoms suggestive of kidney trouble, and in which clinical and ordinary radiographic examination does not completely clear up the diagnosis, should be investigated by this method. Alterations in shape, size or density are at once made clear, also calculi too small or faint to show in the usual manner. A wide field should be the investigation of alterations in the adrenal body—thus the method is not limited to strictly urological cases, but should be used in elucidating certain disorders of the ductless glands.

As to risks, there may be a theoretical possibility of setting up perirenal cellulitis, but no suggestion of any ill effect has occurred in Dr. Carelli's practice. On the other hand, the procedure may turn out to have therapeutic uses, on the lines of Colonel Rost's paper in the BRITISH MEDICAL JOURNAL of December 10th, 1921. Personally, having carefully considered Dr. Carelli's radiographs, and seen his procedure upon the living subject, I have no hesitation in recommending the method as one of very great value.

DEEP X-RAY THERAPY IN MALIGNANT DISEASE.

NOTES OF A VISIT TO ERLANGEN.*

BY

J. CURTIS WEBB, M.A., M.B., B.Ch.,

HONORARY RADIOLOGIST, GLOUCESTERSHIRE INFIRMARY.

During a visit to Erlangen last September I was able to make certain observations which I propose to relate. I will consider the principles underlying this form of x-ray therapy under three heads: (1) Physical, (2) biological, (3) therapeutic.

1. Physical.

Wintz defines his unit skin dose (U.S.D.) as that dose of rays, generated at a special voltage (180,000 to 200,000 volts) by a special tube, and filtered through 0.5 mm. zinc, which, at 23 cm. distance from the skin, produces on the area treated a red blush after five to eight days, and distinct tanning after four weeks. This dose he calls 100, and he expresses in percentages the amount absorbed, and therefore active, at varying depths below the surface. He estimates these percentages by the iontoquantimeter of Szilard, which depends for its action on the fact that electrically charged air is discharged by x rays falling thereon at a rate directly proportional to the quantity, irrespective of quality—that is hardness—of such rays. It consists of a heavily insulated wire, one end of which passes into a closed cardboard chamber (of Bergmann's camera) like a large test tube. The other end is connected to an electroscope, one leaf of which is fixed, and the other held lightly against it by a fine hair-spring. When the whole is charged by a small influence machine the leaves separate. If now x rays be allowed to fall on the camera the air therein is discharged and the leaves come together. The time taken by the movable leaf to pass over a scale lying under it is taken as a comparative measure of the amount of rays falling on the camera. For example, if filtered rays fall direct on the camera, and the electroscope leaf takes 9 seconds to travel over the scale, or in other words to discharge the air in the camera, and if now a box of water, which has the same coefficient of absorption of x rays as the human tissues, of a thickness of 10 cm., be interposed between the x-ray tube and the camera, and it is found that the time taken is 54 seconds, the ratio of the amount of rays received by the camera in the

* Substance of a paper communicated to the Gloucestershire Branch of the British Medical Association.

two cases is 51 to 9, or 6 to 1; that is to say about 17 percent. is still active after passing through 10 c.m. of water. Such an instrument can be used to obtain an accurate indication of the active rays passing through any desired thickness of water or human tissue.

The bundle of rays given out from an x-ray tube consists of waves of varying lengths. The softest rays have a wave length of 1 Angstrom unit (A.U.), which is taken as the unit of wave length measurement, and the hardest are 0.25 to 0.1 A.U. The penetrating power of the softer rays, though they have biological activity, is slight and varying, and the aim of Professor Wintz has been to obtain a radiation that would be penetrating and homogeneous.

To obtain the first of these two qualities it was necessary to secure an x-ray tube that would not only emit a ray bundle which contained the maximum of hard, that is penetrating, rays, but this tube must be capable of sustaining a steady output of these rays for several hours on end. This has been secured, both in the form of the Coolidge tube, and a special form of self-hardening gas tube, with an ingenious method of automatic regulation, which secures the maintenance of a fixed hardness for many hours. To secure an output of these hard rays it is necessary to pass through these tubes a current of far higher voltage than we have been in the habit of employing hitherto. The optimum voltage, taking many other factors into consideration, including the greatly enhanced cost and destructibility of tubes according to the increased voltage, has been found to be 180 to 200 kilovolts; that is, if at these voltages the absorption of rays at 10 cm. deep is 18 per cent. of the unit skin dose, it is only 19 per cent. at 250 kilovolts. The special apparatus devised to give this output, and to maintain it for long periods without breaking down, differs from those in general use in that the latter are designed to pass the maximum current through a medium soft tube for a short time, while the Erlangen technique requires the passage of a small quantity through an intensely hard tube at a very high voltage for long periods.

If dosage is to be accurate it must be capable of being measured—that is to say, it must be possible to state in terms of percentage what proportion of the unit skin dose is absorbed, or active, at varying depths in the tissues. To attain this the ray must be practically homogeneous, a ray, that is, which has been so thoroughly filtered from the rays of longer wave length that, in its passage through the human tissues or other media, it is not further changed in quality, or, as a corollary, is absorbed in fairly uniform percentages by each equal amount of the tissue or other substance. This homogeneity is obtained by filtration of the ray, and Wintz states that with the special gas tubes referred to above it can be secured by using a filter of 0.5 mm. of zinc (= 12 mm. aluminium); in tubes of the Coolidge pattern working at the same voltage and with the same equivalent spark gap it is necessary to use 4 mm. of aluminium in addition to the 0.5 mm. of zinc. When these hard rays pass through the tissues they undergo a weakening, or loss, through each successive centimetre. This loss is made up of absorption plus dispersion; dispersion takes place through the "secondary ray." Wintz divides these rays into three groups:

1. *Beta rays*, which are actually formed in the tissues; they have a small range of action, but are, however, extremely potent, and play a very important part in deep therapy.

2. *Fluorescent rays*, which are very soft, are caused by the rays impinging on the filter or skin. In deep therapy they can be neglected unless the filter is placed directly on the skin.

3. *Scattered rays*, which have the same quality as the primary ray, and may be regarded as automatically generated additions to this ray. They are the most important of the secondary rays.

Their generation is increased as the voltage increases, as the diameter of the bundle of incident rays is increased, and as the rays penetrate deeper and deeper into the tissues.

These facts can each be proved by first calculating what should be the active dose at any given depth under given circumstances; if the accuracy of these figures be tested by the ionoquantimeter it is found there is a definite error, and that the actual is greater than the calculated amount. This error is due to the progressively increasing action of the secondary rays. It is found that the relative absorption at a given depth is increased the further the anticathode is removed from the skin. But this increase is obtained only by greatly augmenting the time of exposure. For example,

if the U.S.D. is reached in 35 minutes at a distance of 23 cm. it will require 165 minutes at 50 cm. and 372 minutes at 75 cm., or over 6 hours, because the intensity of x rays, like that of light, varies inversely as the square of the distance. Nevertheless, in comparatively superficial cancers, for example, scirrhus of the breast, vulva, etc., where the cross-fire method of application is difficult or impossible, where the tumour is very large, or where it cannot be accurately located, this method of application is often necessary.

Wintz states the time of irradiation is not shortened by increasing the quantity (milliamperage) of current passing through the tube. The optimum is about 2 milliamperes, as appears from the following table, for a Furstenau Coolidge tube:

Ma. through tube.	Percentage Dose at 10 cm. deep.
1.0	24.2
1.5	24.0
2.0	24.2
2.5	23.4
3.0	23.0
4.0	21.0
5.0	19.0
6.0	18.0

It has been argued that because the rays are so hard they penetrate without action, but the fact seems to be that it is because the rays are hard that they set up the important secondary, or scattered radiations. In this country we usually employ 4 to 6 mm. aluminium to filter the rays, instead of the equivalent of 12 to 16 as at Erlangen, and the voltages used are too low to generate them in sufficient quantities.

As to the relation of radium to deep x-ray therapy, it is to be noted that the action of radium is local, and does not extend beyond, at the outside, 3 cm. from its source. It follows, therefore, that to attack a tumour of any size a number of tubes must be buried in the growth, which will each produce an intense local necrotic action, but its area of influence rapidly diminishes till, at about one inch away, the dose received by the cancer cells is no longer lethal, but may be actually stimulating. If radium could be obtained in larger quantities it might be different, but as things are its use at Erlangen has been entirely abandoned, save where a purely local action, as in a malignant stricture of the oesophagus, is required.

2. Biological.

The theory on which the efficacy of x rays on malignant growths and on ovarian tissue depends has hitherto been based on the action of the rays in splitting up lecithin—in which cancer cells are exceptionally rich—with the liberation of cholin, an intense poison, which when set free in the cells kills them. Wintz has found that with his technique, and calculating the U.S.D. at 100, the percentage required to destroy the following tissues is—for

Carcinoma cells	100-110 per cent.*
Sarcoma	60-70 "
Tuberculous tissue	50 "
Ovarian cells (to produce amenorrhoea)	35 "
Bowel (normal)	160-170 "
Muscles (normal)	170-200 "
Irritation dose for carcinoma	about 50 "

* Minimum, 50 per cent.

The following theory has been evolved by Dr. W. J. Turrell, of Oxford. It fits in with the work of Dr. Rigand, Director of the Biological Laboratory of the Paris Radium Institute, and I am much indebted to Dr. Turrell for permission to mention it before his forthcoming work—in which it is more fully elucidated—is actually published.

Kohler has obtained microphotographs of the dividing nuclei in the gill plates of the salamander by ultraviolet rays, and has shown that the chromatin substance in these rays, and has shown that the chromatin substance in these nuclei is so opaque to waves of very short length as to appear as though it were deeply stained; he has proved the complete absorption of these short wave lengths by the chromatin. Light is only active when it is absorbed and it is only absorbed when its wave length is in resonance with—that is to say, when its vibration corresponds with—those of the atoms on which it falls (law of Grotrius).

Further, Rigand has shown that certain cells are very sensitive to hard x rays and the gamma rays of radium. A subcutaneous lymphosarcoma can be destroyed without producing any skin changes except the falling out of the

hairs; this result must be due to a selective action of the rays on two particular types of cells—the sarcoma cells and the generating cells of the hair follicles. This selective action appears to depend, not on the nature of these cells, but to be due to certain states or physiological moments in their life, the best known of which is the state of reproduction. The special radio-sensibility of cancer cells is due to their indefinite reproduction. The essence of reproductive power is in the chromatin, and hard rays poison chromatin, acting probably by a process of oxidation or reduction, so setting free a ferment or toxin. If this toxin is liberated in small quantities—as by a slight action of the rays—the action on the other cells would appear to be stimulating; if the action is profound, cell death follows.

This hypothesis of a toxin explains the latent period before the effects of x rays manifest themselves, and as the presence of a toxin in the blood always tends to the formation of a specific antitoxin, there is here an explanation of the fact that in such constitutional diseases as leukaemia much benefit is often derived from the first course of raying, while each subsequent course seems to be less and less efficacious. It is known that when the blood of a leukaemic patient is submitted to x rays leucopenia follows, and attains its maximum after an interval of five to ten days. It is probable that this leucopenia is due to a lencolysin caused by the toxin formed in the blood in consequence of the action of the rays on those nucleated white blood corpuscles whose nuclei are in a specially radio-sensitive state at the time they are exposed to the rays, that is to say, those whose chromatin granules are undergoing karyokinesis.

Curschmann and Gamp have proved that the serum of a leukaemic patient, subjected to repeated raying for a long period, would, if injected into the blood of another leukaemic patient who had not been rayed, cause a destruction of leucocytes, but that the leucocyte count returned to what it was more rapidly after each injection. Can this be explained save on the assumption of the formation of a "toxin" and "antitoxin"?

If further research serves to establish this theory as the true explanation of the action on the tissues of waves of very short length, does it not open the question whether all our methods of x-ray therapy, as far as attacking deeper structures, are not been fundamentally wrong? It has been the custom to use divided doses of medium hard rays spread over a period, each dose being far short of the full lethal dose. In these circumstances have we not frequently only succeeded in creating so much toxin as to stimulate the remaining cells to further activity, and, by allowing time for the production of the antitoxin, to thereby minimize or destroy the value of subsequent applications?

Another intensely interesting speculation which arises is whether it would be possible to ray carcinomata, either artificially produced or naturally occurring in animals, and thus load the blood of the animal with the specific toxin, which could then be injected into human beings, either as a prophylactic or curative agent. There is a strong analogy between such a procedure and the production of diphtheria antitoxin in horse serum. A further question is whether it is possible, prior to treatment, to secure that the maximum number of the growing cells of the tumour should be in the physiological moment of reproduction. This might be effected by giving preliminary small doses of rays designed to liberate so much toxin as should be a stimulant. Lately Wintz had been administering to all his malignant cases a preliminary copper ionization, with a view to the introduction of copper ions into the growth, so as to secure an increase of secondary radiations in the tumour. The majority of electrotherapists are agreed that it is impossible to introduce ions from without deeply into living tissue; yet Wintz claims benefit from his ionization. May it not be that, just as intra-uterine, or even percutaneous applications of the constant current will often cure amenorrhoea, or delayed or scanty menstruation, by stimulating the cells of the Graafian follicles, so the passage of a constant current will stimulate karyokinesis in the cancer cells, and thus bring the maximum number possible into a radio-sensitive condition? For this purpose only a mild, and therefore painless, current would be required.

3. Therapeutic.

This deep therapy has been used successfully in the treatment of carcinoma, sarcoma, tuberculous affections of the

* Wintz has succeeded in inducing amenorrhoea in a patient suffering from menorrhagia by a similar course of injections.

peritoneum, bones, glands, etc.; to produce amenorrhoea and shrinkage of the growth in fibroids; in leukaemia and other blood diseases, and in hypertrophy of the prostate.

It is possible to determine by the ionoquantimeter the exact percentage of the U.S.D. that is active at varying depths in the tissues. Thus, with the U.S.D. at 100, and with apparatus and tube functioning well, the active dose at 10 cm. deep is about 18 per cent. Now, the uterus is situated at about the centre of the circumference of the lower abdomen, and approximately 10 cm. from the skin. If we take the lethal carcinoma dose as 110 per cent. U.S.D., it is obvious that, if treatment be applied from six or seven ports of entry, the rays being directed on to the uterus, the skin in each area will only receive the U.S.D., but at the centre of this converging bombardment a total of 6×18 or 7×18 —that is, 108 to 126 per cent.—will be reached. Similarly, as the dose at depths other than 10 cm. is equally well known, it is but a matter of calculation, and consequent arrangement of the cross-fire, to secure the "carcinoma dose" on to any malignant disease so situated that the cross-fire method can be employed.

In malignant disease situated in or closely under the skin and where, therefore, this cross-fire method is not available, the problem is totally different. Let it be supposed that the case is one of scirrhus of the breast, or of vulvar carcinoma, where the disease extends only 3 to 5 cm. deep. Every cell of such a growth must receive at least the minimum dose (90 per cent. U.S.D.), but, with the 23 cm. focus distance and field of 6×8 , the dose received by the cells at the lowest part of the growth is only about 60 per cent., and the irritation dose, which causes an increase in the growth of cancer cells, is just about this figure.

Seitz and Wintz have found by experiment:

1. That increasing the distance of the anticathode from the skin increases the percentage of rays that are active at a given depth. Thus at 3 cm. deep, and using a field 6×8 cm., the percentage of rays absorbed is as follows:

If the anticathode is 25 cm. from the skin	...	60 per cent.
" " 30 cm. " " "	...	66 " "
" " 50 cm. " " "	...	70 " "

2. They have further proved that the depth dose is improved by increasing the size of the impact field. Thus at 3 cm. deep, and at 30 cm. distance, the percentage absorbed is as follows:

With an impact field of 15×2 cm.	...	47 per cent.
" " 6×8 cm.	...	66 " "
" " 10×15 cm.	...	77 " "

3. By a combination of these two factors—that is to say, by increasing both the distance of the tube from the skin, and also the impact field, it has been proved that at 3 cm. deep:

Size of Impact Field.	Distance of Anticathode from Skin.	Amount of Rays Absorbed.
9×12 cm.	30 cm.	74 per cent.
10×15 cm.	50 cm.	86 " "
9×12 cm.	80 cm.	86 " "
10×15 cm.	80 cm.	90 " "
9×12 cm.	100 cm.	90 " "
10×15 cm.	100 cm.	93 " "

It is thus seen that it is possible to reach the minimal "carcinoma dose" even in the lower lying cells of superficial cancers by greatly increasing both the field of impact and the distance of the anticathode, but this can only be attained by enormously augmenting the time of exposure. If at 23 cm. the U.S.D. is reached in forty minutes, at 80 cm. the time required will be approximately eight hours. As far as possible the dose lethal to the cancer cells is given at one sitting, and the after-effects on the blood are combated by injections of one of the arsenic preparations.

The most important matter is to decide how far this treatment is an adjuvant to, or substitute for, operation. At Erlangen operation is practically entirely dispensed with, save in cases of primary carcinoma of the ovary, except where it is required for a subsidiary purpose—for example, colostomy before treating a carcinoma of the rectum, to ensure rest to and absence of irritation of the part, or gastroenterostomy, or other short-circuiting operation, where obstruction is threatened.

Personally, I am uncertain whether at the present time the results of this deep x-ray therapy have yet reached such a point of certainty that it is advisable, in the patients' interest, to dispense with operations, but I am convinced that the severity of the operations can be minimized in cancers of the uterus and cervix. I believe the best treatment to be pre-operative raying. After six weeks the patient should be re-examined, and the local disease will then

probably be found to be on the road to cure, and the para-metria can be attacked. If operation be necessary, certainly Wertheim's is not required.

In scirrhus of the breast I believe the local removal of the growth to be desirable, but not the removal of the axillary glands. By taking away the filters one tends to spread metastasis, but these cases should have a pre-operative and a post-operative raying.

Cases of malignant disease may, from the point of view of treatment, be divided into four classes: (1) Easily operable; (2) operable, but where there is every probability of there being inoperable extension of the primary growth; (3) hopeless for operation owing to position—for example, head of the pancreas, spinal cord, etc.; (4) inoperable owing to fixation of organs, extension of the disease, etc.

In Class 1 I believe in operation, followed by deep raying, and in Classes 2 and 3 in deep therapy alone; in Class 4 it is very difficult to decide. Nothing, save perhaps alleviation, can be hoped for from deep therapy, and, after the position has been fully explained to the patient or his family, the decision must rest with them.

When I was in Erlangen I asked for statistics, but was told that, at any rate as far as malignant cases were concerned, it was as yet impossible to give definite figures. The reason is evident, for this form of treatment was begun only a short time before the war broke out, and was then in the purely experimental stage. During the war, though Professors Seitz and Wintz were able to carry on some experiments, they were not able to obtain all the necessary instruments to carry out treatment on a large scale. Investigations were pursued to ascertain the best form of generating apparatus, of filters and of tubes, to find out the exact dosage that would cause the cessation of the menses, and would cause the death of malignant and other cells. The former result has been definitely attained. Wintz has published a report of 500 cases of uterine haemorrhage, due to fibromyomata, the menopause, and other causes, which have all been cured by one single treatment in each case. Dr. Ernest Stark, practising the same treatment in the provincial clinic at Weiden, reports 19 cases with only one failure, which was attributed to the use of an insufficiently powerful apparatus.

The failure or success of applications for such purposes is almost at once evident, but the position is different when the results of the treatment of malignant disease are under consideration. To speak positively on the subject of "cure" the standard of five years' freedom from recurrence after treatment is generally accepted; consequently cases treated subsequent to 1917 must be ruled out. But it was only about this date that the technique was perfected, or that sufficient instruments, tubes, etc., could be secured to treat a number of patients sufficient to afford the required data.

Again, it is to be remembered that the earlier a malignant case is subjected to deep x-ray therapy the better is the prognosis. But it is just these early cases that are also best from a surgical standpoint, and it is only natural that some time must elapse before an old and accepted treatment is supplanted by a newer one. Patients with cancer of the female generative organs go direct to the gynaecological clinic, of which Professor Wintz is the director, and can therefore be rayed when in the early stages of the disease, but with this exception the majority of cases of malignant disease treated by deep therapy are either primary inoperable cases, or patients with secondary deposits or relapses. These cases are naturally more unfavourable than early primary ones, and hence statistics would not be nearly as good as if it were possible to select purely suitable patients—as surgeons are able to do.

I saw several cases of malignant disease of the cervix and uterus which had been rayed as long as three and a quarter years before, in which there was no evidence of the disease to be detected on examination, and the patients had put on weight, felt well and were able to work—in fact, were apparently "clinical cures." I saw a man who had had a large fixed tumour the size of half a coconut on the left side of the neck; an excised piece had shown it to be a lympho-sarcoma. He had been rayed twice, the first time ten months earlier. When I saw him the lump was about the size of half a tennis ball, painless, and freely movable. It was apparently simple fibrous tissue. The man had lost his pain and dysphagia, and was well and working. A case of periosteal sarcoma of the head of the humerus showed, both clinically and by x rays, an equally good result, as did a case of scirrhus of the breast treated two years previously. In

none of these cases was any operation performed, except the removal of a small piece for diagnostic purposes.

The chief assistant at Wertheim's clinic in Vienna, who was at Erlangen at the same time as I, told me the results of this treatment in cancer of the uterus or cervix are so good that Wertheim's operation is gradually being abandoned in that clinic; it must, however, be remembered that owing to the central position of the uterus in the body it is ideally placed for "cross-fire" application, which is the most favourable method.

It has not been possible to read all the literature—even if one could obtain it—which has in recent years been published in Germany on this deep therapy. Suffice it to say that analyses and criticisms of the method have been produced, not only by the Erlangen school itself, but also by such authorities as Wernke of Berlin, Martins of Bonn, Frankel of Freiburg, Döderlein of Munich, Stark of Weiden, and many others. In most cases both successes and failures are impartially described and efforts made to explain the one or the other. From what I have read and what I learnt from those with whom I talked on the subject (and while in Erlangen I had the chance of discussing the subject with the professor of gynaecology in the University of Barcelona, with the physicians in charge of the x-ray and radium department in the University of Stockholm, and with the chief assistant at the clinic of the late Professor Wertheim of Vienna) I have formed the opinion that all who have had practical experience of the Erlangen treatment are most favourably impressed by it. As far as I can see, its detractors are those who have prejudged it on theoretical grounds, or on account of bias because of sensational publications.

The general inferences to be drawn from publications—and among the writers are surgeons as well as radiologists—and from my own impressions may be briefly summarized as follows:

1. That this form of treatment is a fundamental and epoch-marking improvement on pre-existing methods of x-ray therapy, and is the technique to be adopted in all cases (other than purely superficial skin lesions) where this form of therapy is indicated.

2. That, as in all other treatments, the earlier a suitable case is treated, the better are the results.

3. That it is the treatment of choice in all cases of menorrhagia or metrorrhagia in patients over 38, provided that suppurative disease of the tubes or ovaries be excluded. Eden and Provis (*Lancet*, February 12th, 1921) are in agreement with the use of x rays in these conditions, though they differ from the German school in excluding cases of malignant disease. It must, however, be remembered that they were not employing the Erlangen technique.

4. All the foreign authorities agree as to the immense value in every malignant case of either pre- or post-operative raying, or both, according to circumstances, and the majority—excluding Professors Seitz and Wintz and their immediate disciples—recommend operation according to the conditions that I have laid down above.

5. Great use is made of deep x-ray therapy in tuberculous disease of the glands, bones, joints, bladder, and peritoneum as an auxiliary to other treatments. If in tuberculous glands there be a caseous focus, such glands will break down under the treatment.

Personally I am convinced that this new therapy has opened up a fresh avenue of treatment, and has enormously increased the field for the curative use of x rays. Much was hoped for, and much disappointment has been experienced in the past from x-ray therapy in malignant and other diseases, but the researches of Professors Seitz and Wintz into the production of homogeneous rays and their accurate measurements, and into the absorption of these rays at varying depths in the tissues, and the practical results obtained at Erlangen and elsewhere have, I believe, carried us far along the road the end of which is the satisfactory treatment of that which was previously considered hopeless, and has simplified and expedited the cure of many other conditions—for example, fibroids and menorrhagia—the treatment of which has, up to the present, lain solely in the province of surgery. The British Association for the Advancement of Radiology and Physiotherapy, in issuing a warning to the public in connexion with the Erlangen treatment for cancer, said:

"We are, however, of the opinion that a closer co-operation between the surgeon and the radiologist would lead to a clearer appreciation of the value of radiation in treatment, and that, in all cases, both surgery and radiation therapy should be considered with a view to making the fullest use of both."

Advance will only come by this closer co-operation. It is not enough for the surgeon to order pre-operative or post-operative raying as his special predilection dictates. Deep therapy opens a newer and a wider field, and establishes the position of the medical radiologist as one to be called into consultation with the surgeon over a case; and to co-operate with him in deciding whether it is one for operation, for deep therapy, or for both.

CASE OF TRYPANOSOMIASIS FROM PORTUGUESE EAST AFRICA APPARENTLY CURED.

BY

GEORGE C. LOW, M.A., M.D., C.M., M.R.C.P.,

SENIOR PHYSICIAN, HOSPITAL FOR TROPICAL DISEASES, ENDSLEIGH GARDENS, N.W.,

AND

H. B. G. NEWHAM, C.M.G., M.D., M.R.C.P.,

WARDEN OF STUDIES AND DIRECTOR OF PATHOLOGY, LONDON SCHOOL OF TROPICAL MEDICINE, N.W.

BEFORE one can speak of a definite cure in human trypanosomiasis some years of perfect health must elapse after the cessation of all treatment. Suggestions, such as have recently been made, of curing patients by one injection into the spinal canal of salvarsanized serum are, to say the least, of doubtful value and tend to indicate that the maker of them is ignorant of the literature of the subject. Judged by the test of time indicated above, however, there are quite a number of cases of infection with *Trypanosoma gambiense* that have been treated in England with successful results and are still alive years after their infection. (Cases of Manson and Daniels.) It is right to state, nevertheless, that this happy result has not been attained in all cases even of that infection; we know of two patients who have died recently of sleeping sickness, even though well treated over prolonged periods of time.

In infection with *Trypanosoma rhodesiense* (including under this term Portuguese East African infections) the prognosis is very grave, and down to the present date perhaps only one case of a European¹ can be said to have been cured (Mr. H., a case of Dr. Daniels). We have recently heard that this patient is at present farming in Rhodesia and is enjoying perfect health. The next best result we know of to this was the case of G. (under the care of Sir Patrick Manson and Dr. Daniels); who lived for two years and three months after infection. Though thoroughly treated with antimony and atoxyl, this patient died of sleeping sickness with typical lesions in the brain.

We have now the records of another case, that mentioned in the title to our paper, who is still alive three years after acquiring the disease in Portuguese East Africa, and who is at present apparently well and in a good state of health. One of us (H. B. N.) saw this patient in Dar-es-Salaam in 1918 and has already published a note about him,² while later Dr. W. A. Murray, under the heading of "Notes on the Successful Treatment of a Case of Sleeping Sickness," gave further details of his treatment and stay in Durban up to the time when he was transferred to the South African Institute for Medical Research, Johannesburg, on October 8th, 1919.³ From that time till April, 1921, when he was sent home to England, Dr. Watkins-Pitchford, the Director of the Institute, has had him under observation and has very kindly supplied us with the details of his stay there. Finally the patient reached England on May 17th, 1921, and came direct to the Hospital for Tropical Diseases, where he has been under our observation since.

History of Case.

The patient, as far as can be judged, was infected about October 9th, 1918, in the Lugenda River valley while on the march between Alto Moluene and Nyemano, Portuguese East Africa. On October 15th he reported sick with a temperature, but rejoined his battalion on the 19th. On the 20th he noticed a swelling in the right axilla and was admitted into Ndanda Hospital on October 25th with a temperature of 102°F. and treated as a case of malaria. From there he was transferred to Lindi Hospital (November 14th, 1918), where a patch of cutaneous erythema with infiltration was noticed in the right mammary region and a general adenitis was detected. An examination of the blood on the 16th by Captain Butler showed trypanosomes. On November 25th, 1918, the patient was sent to Dar-es-Salaam Hospital, where

he was seen by one of us (H. B. N.). On arrival the patient was anemic and stated he had lost weight. The pulse was rapid, the spleen just palpable. An erythematous rash was seen on the trunk. There were one or two well-marked rings, but generally the rash was of a blotchy character. No local oedema or adenitis was found. Kerandel's symptom was absent. There were no eye symptoms. The temperature on admission was 100.8°F.

Examination of the blood: Total red cells, 2,672,000; total white cells, 4,800; lymphocytes 26 per cent.; large mononuclears 17 per cent.; polymorphonuclears 51 per cent.; eosinophiles 6 per cent. Scanty trypanosomes were found. Treatment with intravenous injections of antimony was at once begun, but the patient did not stand the first injections at all well. On January 9th, 1919, he was transferred by hospital ship to Durban, where he passed under the care of Dr. Murray. On admission there the following points were noted by Dr. Murray.

Dr. Murray's Notes.

Weight 11st. 4lb., one stone below normal. Weakness is marked, but he can walk about, and sleeps and eats well. There is no oedema, no hyperaesthesia of muscles on pressure (Kerandel's sign), no cramps or pains in bones. The heart appears to be normal; urine normal; spleen enlarged. There is general glandular adenitis, with a red rash over the right chest.

Blood smears: Numerous trypanosomes present, also B.T. malarial parasites. Blood count: Red cells, 3,300,000; white cells, 5,500; haemoglobin 55 per cent. Differential count: Polymorphonuclears 40 per cent., large mononuclears 20 per cent., lymphocytes 24 per cent., eosinophils 6 per cent., mast cells 1 per cent., myelocytes 2 per cent., leucoblasts 2 per cent., broken nuclei 5 per cent.; a few normoblasts were present. Blood pressure 120 mm. Hg.

A rabbit and guinea-pig were injected on January 28th, 1919, each with 1 c.cm. of the patient's blood. The rabbit showed trypanosomes after thirteen days; and died in ten weeks. The guinea pig first showed trypanosomes after eleven weeks, and died in nineteen weeks. The trypanosomes were polymorphic, and posterior nuclear forms were found. A prolonged course of treatment was commenced on January 21st, 1919, as recommended by Dr. Newham (see below), and this was kept up till the patient was sent to Johannesburg.

Dr. Watkins-Pitchford's Notes.

The patient was admitted into the South African Institute for Medical Research, Johannesburg, on October 8th, 1919. Weight 11st. 1lb. He was kept under continuous observation and treatment until May 7th, 1920, by Dr. J. H. Harvey Pirie. The examination of the daily blood specimens was undertaken by Dr. Annie Porter, who found a few *T. rhodesiense* (many of which were degenerate forms) upon the day of admission and upon each day, with one exception, up to October 17th, 1919. The numbers were small, 3 per cubic millimetre at most. Although daily examinations (thick films) have been made from the last-mentioned date until April 8th, 1921, no further trypanosomes have been detected.

It is worthy of note that trypanosomes had not been detected in the blood for forty days prior to admission to the institute, the last occasion upon which Captain Murray, of Durban, found them being August 29th, 1919. Although treatment had not been interrupted during these forty days, trypanosomes were found; as stated, upon each of the first eight or nine days of the patient's stay in the institute. The question arises whether the change in altitude and temperature associated with his transference from Durban to Johannesburg had brought about the reappearance.

On May 7th, 1920, the patient was allowed to go home (Premier Mine, near Pretoria), the treatment being continued by Dr. Gow, daily blood specimens being sent to the institute for examination. The patient again attended the institute, this time as an outpatient, from December 18th, 1920, to April 8th, 1921.

The administration of soamin and of antimony oxide were stopped shortly after his admission on October 8th, 1919, tartar emetic only being given. This was administered intravenously in 2 grain doses twice a week until the end of October, 1920, and once a week from then till April 8th, 1921.

His total medication with arsenical and antimonial preparations from the date of commencement, November 19th, 1918, four days after trypanosomes were first discovered, till April 8th, 1921, has been:

Atoxyl	13 grains
Soamin	234 grains
Nucleositol	13.5 c.cm.
Galy	0.5 gram
Liq. arsenicalis	— a little on hospital ship between Dar-es-Salaam and Durban				
Tartar emetic	363 grains
Antimony oxide	4.75 grains

The patient was also infected with benign tertian malaria when in East Africa. He had regular quinine administration during most of the time he was under treatment in Durban. Dr. Murray states in his notes of July 7th, 1919: "No malarial parasites were seen in blood films since January, 1919"; and on that date the administration of quinine was stopped.

No malarial parasites were found in the blood films while he was at the institute until, without any rise of temperature or other symptom, they were found in considerable numbers on March 17th, 1920, and in small numbers the following day. Quinine administration was recommended, and continued for a considerable period. Malarial parasites have not again been seen.

His weight at the cessation of treatment was 11st. 3lb., which is only a few pounds under his normal pre-war weight. During treatment he had been down to as low as 10st. 3lb. He did a

certain amount of office work after January, 1920, and the improvement in his mentality as the result of having some occupation was obvious. It was noticed, however, that he was very shaky and inclined to be "jumpy," and it was apparent that he was about reaching his limit of toleration of injections. During the whole time of the patient's association with the Institute his observation and treatment were entrusted to Dr. J. H. Harvey Pirie.

The patient left Africa on April 29th, 1921, and arrived in London on May 17th, 1921. He came direct to the Hospital for Tropical Diseases, where he has been off and on to the date when this paper was written (November, 1921).

On admission there was little, if anything, to note: no fever, no enlargement of glands, no splenic enlargement—in fact, no definite signs of the disease. It was resolved then to stop all treatment and watch very carefully the results, the patient in the meantime living an ordinary life, going and coming from the hospital from time to time, just like an ordinary person. Blood examinations were uniformly negative for trypanosomes and malarial parasites, and inoculations into guinea-pigs and rats gave negative results. The only thing that one could say was wrong was that the patient did not feel as strong as he used to, and there was a fine tremor just visible in the hands.

In July, 1921, during one of his spells in hospital, he complained one day of the sight in one eye; he was examined by Colonel R. H. Elliot, who reported that there was a patch of paracentral choroido-retinitis in the right eye, a condition, as far as we know, only twice before reported in human trypanosomiasis (a case of Sir Patrick Manson's, the first case of trypanosomiasis at the London School of Tropical Medicine, in 1902; and one by Morax in 1910 associated with cyclitis¹). This observation is of very great interest, as it records a third case of this condition, though other cyclitides (for example, cyclitis) are not uncommon and have been described by Daniels and others. Whether the condition has existed from the beginning of the infection or came on later in the course of the disease is not clear.

The question now arises, Is the patient cured of his infection? It is difficult to say definitely whether this is so or not. One point against it is that the tremors of the hands seem to be definitely increasing and the general condition, though very good, on the whole does not appear in some ways to be perfect.

During the autumn months the patient was in the country and kept well, with no complaints. He stated on his return that he had had no fever whilst he was away, and had been able to play a hard game of tennis without in any way getting exhausted. He returned to hospital for another examination in November, and we got Dr. Gregg to do a lumbar puncture in order that an investigation of the cerebro-spinal fluid might be made.

The fluid obtained was perfectly clear, with no increase of pressure. Microscopically the cells were normal in number, a few lymphocytes were present, and there were no signs of trypanosomes. The Wassermann reaction of the fluid as well as of the blood was negative.

This would seem to indicate that cure has taken place, but it does not absolutely prove that this is so. All that remains, then, is to observe the case for a longer period of time before definitely coming to the conclusion that he is really free from his infection, and we propose to do this and not to give any more treatment for the present.

As the patient's home is in South Africa he is going to return there, and he will notify the authorities at the Institute for Medical Research at Johannesburg if any further symptoms develop. His future progress can also be controlled there, and it will be of great interest to see what that will ultimately be.

ACCORDING to the records of thirty-seven leading American insurance companies, the year 1921 was the healthiest in the history of both the United States and Canada. It is stated that during that year influenza almost disappeared from the United States and Canada, and that pneumonia decreased by 50 per cent. as compared with 1920. On the other hand, the mortality due to automobile accidents showed an increase of 15 per cent.; the number of deaths from this cause was in round numbers 10,000. Homicides and suicides also showed large increases, being four times more frequent than in 1920.

THE SIGNIFICANCE AND TREATMENT OF SOME ABNORMALITIES OF THE URINE IN CHILDREN.*

BY

A. DINGWALL-FORDYCE, M.D., F.R.C.P. EDIN.,
PHYSICIAN, ROYAL LIVERPOOL CHILDREN'S HOSPITAL; LECTURER ON
DISEASES OF CHILDREN, LIVERPOOL UNIVERSITY.

WHEN we are called upon to give a diagnosis in the case of a child, and to follow this up with prognosis and treatment, we seek for assistance from family and personal history, we study symptoms, and we determine facts. History may be elusive, is often imperfect, and sometimes unreliable; the recognition and valuation of symptoms is largely a matter of experience and opportunity, and, lacking these, perspective is imperfect. But the determination of facts is in the hands of every medical graduate, and one important means of search for facts is thorough examination of the urine. Certainly, in any doubtful or continuing illness general examination is incomplete without chemical and microscopical examination of the urine. In this paper I wish to discuss certain facts in urine examination and certain difficulties in the determination of their significance.

Bacilluria.

The first is a fact determined by microscopic examination of the urine—the finding of pus cells and motile bacilli. What is the significance of the fact? In the cases of healthy children, are motile bacilli and pus cells commonly present in catheter specimens of the urine? We may certainly answer, No.

But points of clinical difficulty arise in attempting to advance a step further. In apparently healthy children we rarely feel called upon to use the catheter for obtaining a specimen of urine for examination. If careful precautions as regards cleanliness, retraction of parts, asepsis, etc., are taken, do we find pus cells and motile bacilli present in the urine of healthy children? The answer here must be guarded, because we do sometimes find, in cases of perfectly healthy children, rare cells resembling pus cells and a scanty number of various micro-organisms, which in many, if not all, cases are probably present because of unavoidable contamination. But we may safely say we never find large numbers of pus cells and immense numbers of motile bacilli. While, however, this is true of perfectly healthy children, it is not true of certain children apparently in fair normal health.

I have at present under observation seven children whose mothers consider them in fair average health, who are, in the ordinary acceptance of the term, well, and whose urine, on regular microscopic examination, is found to be swarming with motile bacilli and to contain a distinct amount of pus. I also have reports of four other children, seen in private during the past year and not within the past three months, and who were carefully, thoroughly, and apparently successfully treated for acute pyelitis, and on recent examination of the urine I find that in one out of the four pus cells and motile bacilli are present in large numbers, although the child is apparently well.

It is quite certain that there must be a considerable number of children—probably mainly girls—who are "well" or "fairly well," or it may be, "out of sorts," who are going about, with or without medical attention, and in whose urine motile bacilli and pus are present in quantity. What exactly is the condition? Why is it present? By what dangers, if any, is it attended?

The condition is not tuberculous and it is not due to calculi. There may be no urinary symptoms of any kind, but enuresis sometimes occurs. Renal efficiency is good. The urine is acid; it may show perceptible haziness with cold nitric acid, or it may not. When a fresh drop of urine is examined under the high power of the microscope, pus cells are seen in considerable or large numbers, and along with them great numbers of motile bacilli. If a catheter specimen is obtained and a report prepared by a laboratory, these bacilli are determined to be of the "coli" group, or "para-coli" or "meta-coli" or "pseudo-coli" group! In some cases cocci are also present. No casts are present, and usually no blood cells and no crystals. The general nutrition

* A paper read before the Liverpool Medical Institution, October 27th, 1921.

is fair, but the child is not fat. There is no fever. Constipation is, I think, always present, and it is often most intractable. There is often extensive caries of the teeth. The children, as a rule, are not undersized. All my cases have been girls.

We have to deal with a chronic infection of the urinary tract by bacilli of the nature of some form of the colon type. Catheterization of the ureters in young children cannot be carried out, and, consequently, it is not justifiable to define more accurately the locality of infection.

Important points we must bear in mind are these:

In 90 per cent. of cases in which the urine of healthy female infants under 2 years of age is drawn off by catheter under complete aseptic precautions, bacteria are found in it, mainly bacteria of the coli group.² Similar examination in cases at a greater age shows the urine to be sterile.

A temporary bacilluria is not uncommon in critical, acute, and continued illnesses accompanied with marked prostration.

Acute pyelitis occurs twice as often in babies as in older children.

A great deal of importance is laid on the relation between full control of the bladder sphincter in girls and bacilluria. The frequency of urinary infection by *B. coli* in female infants and the frequent occurrence of the symptom of enuresis in older girls in whom this infection can be noted is striking.

There has been much discussion as to the method of infection of the urinary canal. In female infants it may be impossible always to prevent an ascending infection, but obviously digestive disorder and diarrhoea must favour the passage. In older children, likewise, all marked digestive disturbances must favour infection by one means or another.

In many of the cases of the type of which I speak—chronic "colon" urinary infection—no definite history of an attack of acute pyelitis can be obtained. We do not know whether many of the cases have commenced acutely or not. In some probably a chronic course is run throughout with eventual cure. In some, acute pyelitis first attracts attention. In none is the general health really satisfactory, though it is often impossible to tell from consideration of the general health and physical examination whether bacilluria and pyuria are present or not. Microscopic examination of the urine alone shows, and such examination should be made in the case of every ailing child with doubtful or continuing disability.

If the condition is found to be present and the child "well" she may be considered "merely a carrier" or the type of bacillus present "non-pathogenic." But a child with long-standing continuance of pus and coli-like bacilli in the urine is one in imperfect health, who may at any time develop acute urinary inflammation as a sequel to comparatively trivial affections in practically any part of the body. We know little of the interaction of bacteria, and a chronic "coli" urinary infection can be powerfully influenced by totally different infections elsewhere. Further, it is possible that a reverse train of events may occur in some cases and the urinary infection produce far-reaching secondary effects.

When we turn to treatment we must of necessity divide it into two categories: (a) preventive, (b) therapeutic.

Preventive treatment consists in such dietetic and general hygienic measures as will ensure good digestion, a healthy mouth, normal evacuation of the bowels, and the absence of irritation or excoriation in the region of the perineum. The importance of such treatment from every possible medical point of view is of course self-evident, as it must form the basis of healthy childhood. Its proper carrying out, however, requires attention to many details, none of which should be neglected by the medical man. Its essence is correct diet and no septic foci.

Therapeutic treatment is at present greatly influenced by two conditions—namely, the infrequency with which urine is examined microscopically except in acute cases or cases with marked urinary symptoms; and, secondly, the prominence given in cases of acute pyelitis to treatment by alkalis, urinary antiseptics and vaccines.

The importance of microscopic examination of the urine I have already emphasized.

Acute pyelitis in infants, in the absence of pyelonephritis, can almost always be cured by sufficient dosage of alkali: urotropine and salol are useful in some cases, and autogenous vaccines are sometimes of value in cases of older children and in relation to acute attacks or relapses.

But in the cases of which I speak—the chronic cases with few and indefinite general symptoms—all such methods of treatment are extremely unsatisfactory. The only means of

eradication of the firmly installed bacilli is the restoration to health of the various bodily functions. By all means let us use the above remedies as they may seem indicated in the individual case, but, above all, let us employ scrupulous care in our search for focal sites of infection, for the nature of disturbances of digestion, and for any other abnormalities whatsoever in the child. Let us devote our first attention to the securing of healthy orifices, healthy mouth and healthy intestinal canal, and we have taken the first serious step forward in what, even then, is often a long-drawn-out cure.

Presence of a Reducing Substance.

The second abnormality with which I wish to deal is that of the presence of a reducing substance in the urine.

We are examining the urine of, let us say, a thin, rather poorly developed girl of 6 years, and we find a positive sugar reaction. Is she diabetic? From our undergraduate days probably we have remembered and been influenced by the statements—"sugar is rarely found in the urine in children," and "diabetes in a young child is almost always rapidly fatal." For the moment, however, let us wash the slate clean and ask ourselves with an open mind—Is it uncommon, when testing the urine of a child for sugar to get a positive reaction? The ordinary clinical tests for sugar in this country I take to be Fehling's solution and Benedict's solution. Both in the method of their use and in the interpretation of results there are many possible fallacies. Fehling's solution I have used according to the second method mentioned by Cammidge; Benedict's solution as described by Benedict.

Having for some time been much impressed by the reactions obtained in many cases, I recently took 100 unpicked cases to determine impartially the results of examination. The urine of 50 consecutive out-patients and of 50 in-patients of a hospital were examined, the ages of the patients ranging between 2 years and 11½ years. Of these 100 urines, 19 gave a positive reaction, in all cases very slight with Fehling's solution, and in most, but not all instances, confirmed with Benedict's. In some of the positive cases (9) I proceeded further to a fermentation test with yeast and got positive reactions in 6. In others (6) I sent the specimen to the laboratory, and got reports in 2 cases that the reducing substance was not glucose and in 4 either that it was glucose or was probably glucose.

Thus in 19 per cent. a positive reaction was obtained with Fehling's solution, and in 10 out of 15 of these specimens, on further examination, evidence was obtained of the presence of sugar. In this particular series of 100 cases, then, evidence of sugar in the urine was certainly present in 10.

These results would show that it is not uncommon to find clinical evidence of the presence in small amount of a reducing substance in the urine of ailing children, and that in many of these cases the reducing substance is some form of sugar. In all of these particular 100 cases the amount present was small and consequently the test reactions slight. How are we to account for the textbook statement that "sugar is rarely found in the urine in children"? There are three possible explanations, and I think the full explanation includes all. They are:

1. Lack of systematic examination of the urine for sugar;
2. Variations in sugar content of the urine in different districts; and,
3. Estimation of test results as negligible or "physiological."

As regards testing for sugar, this is obviously desirable in all cases. The test with Fehling's solution, as also confirmation with Benedict's, is readily carried out, though attended with various fallacies so far as a positive diagnosis of glycosuria is concerned. The tests should not be hurried, and if found positive even in slight degree, definition of the reducing agent present as a sugar or not a sugar can be conveniently made by reaction with yeast in a saccharimeter tube. In the series of 100 cases just quoted, sugar was found to be the reducing agent present in two-thirds of the cases showing a positive reaction.

Is it likely that the sugar content of the urine varies in different parts of the country? Sugar, we know, is normally present in the blood and in the urine in amount conditioned by complex processes of metabolism. The liver, the pancreas and the thyroid—to mention only a few of the important organs—are closely associated with its absorption, utilization and excretion. The nervous system is intimately affected.

Varying conditions of climate, diet—of hygiene generally—often affect in a degree so marked as to be obvious the grosser results of differing function of these organs and systems—for example, goitre, asthma. We cannot deny the possibility of a difference according to locality in the degree of frequency of excretion in the urine of a reducing substance in detectable clinical amounts.

This leads to the third consideration: Should such minor test results as those I am discussing be considered negligible and physiological or not? I think they should always be noted, however slight and however fleeting they be, and an explanation sought. It is possible that most, if not all, children from time to time may give detectable sugar reaction on examination of the urine, but even so this forms no foundation for an argument that the detection of such a reaction is of negligible significance.

If once found, examination of numerous specimens should be made—of the twenty-four hours' urine and also of morning and evening specimens. In a large proportion of cases the presence of a positive test corresponds with indiscretion in diet or digestive disturbance, and disappears on correction of such. In other children with indigestion and constipation the reaction is completely negative. This point is in itself important, as possibly affording evidence of individual idiosyncrasy in carbohydrate metabolism.

Another important line of consideration is demonstrated by the findings in the following case.

A girl, aged 6 years, has been under observation in hospital for several months suffering from what I suspected might be progeria. The urine was healthy. She developed a large abscess in the face with considerable sloughing, and the urine showed a distinct positive sugar reaction. The abscess is now healed and the urine free on any reducing agent.

Here was a well-marked case of "sapræmic glycosuria." The precise nature of the reducing substance or substances in the urine during the period of suppuration was not determined, but the fermentation test with yeast was positive and the urine after the abscess healed was free from sugar. I am not now concerned with the nature of "sapræmic glycosuria," but with evidence that slight positive urine reactions should lead to search for a septic focus.

The precise nature of the sugar present in a specimen of urine cannot be determined without expert laboratory assistance; and the examination of blood sugar is, in my experience, valueless except in the hands of a skilled worker in constant practice. The fermentation test with yeast is, however, simple, and in the presence of a positive fermentation test we are faced with the possibility that the reducing agent may be dextrose (glucose or grape sugar), or laevulose (fructose or fruit sugar), or both. (I am not here dealing with nursing infants suffering from gastro-enteritis, in whose urine lactose may be present.)

It has been proved that the presence of laevulose in the urine may be regarded as a sign of liver inadequacy. Laevulose often appears in the urine along with dextrose in marked clinical cases of diabetes. It may, however, appear alone and be derived from cane sugar, honey, vegetables, fruits, etc., in the diet. When it appears it is, as stated above, to be regarded as a sign of liver inadequacy. If, with this in mind, we now turn to the clinical aspect of cases in which we find traces of a sugar present in the urine, we find that in many there is definite evidence of attacks of acidosis; in many there is a history of recurrent attacks of "biliousness"; and in most there is what one may term a full fatty diet. In fact, clinical evidence goes to show that in most there is evidence of strain on liver function, and it seems reasonable to conclude that the small amount of sugar in the urine is probably laevulose. This is further borne out by the satisfactory result of treatment by reduction of fat intake and, if necessary, restriction in amount of other elements in the diet.

But in a considerable proportion of the cases in which only a small amount of sugar is present in the urine, and in the great majority of cases in which the sugar is present in large amount, the sugar is dextrose—that is, the patient has glycosuria. What is the significance of this fact? It is outside the scope of this paper to consider cases either of intermittent or of persistent glycosuria in which large quantities of sugar can be demonstrated in the urine. In all such cases we obtain expert laboratory assistance, determine the level of the blood sugar and the nature of its reaction to a dose of sugar, and also the leak-point for sugar. But whatever

results we obtain, our treatment must be that of diabetes mellitus.

It is with cases which show minor results on urinary examination that I wish to deal. In the majority of them there is no marked polyuria, and there may be no excessive thirst or wasting.

The presence of glucose in the urine is, we know, the chief sign of the existence of diabetes mellitus, but we also know that a small detectable amount of glucose in the urine may exist in the presence of sound health. Glycosuria is a term the interpretation of which in any individual case lies somewhere in a scale extending from sound health at the one extremity to diabetes mellitus at the other.

Cambridge, speaking of transitory, intermittent, and persistent glycosuria and diabetes, says: "It is important that it should be clearly recognized that each is but a phase of the same metabolic error, and that no hard-and-fast line can be drawn between them." He further speaks of a "pre-glycosuric stage." The obvious truth would seem to be: watch for the earliest beginning of abnormality and attempt to check it, as otherwise it may develop into uncontrollable disease.

The markedly outstanding lines along which to attempt to check development are dietetic—a well-balanced diet with the avoidance of constipation and intestinal putrefaction—and aseptic, the removal of all discoverable foci of infection.

My subject deals with small things and is mainly concerned with the beginnings of disease. For fuller development it requires blasts of clinical ozone to play around the figurative laboratory frog.

BLOOD PRESSURE OBSERVATIONS IN FUNCTIONAL BRUITS IN CHILDREN AND YOUNG ADULTS.

BY

A. F. MARTIN, M.D., CH.B.VICT.,
BRADFORD.

During convalescence from various mild infections children often go through a period in which they exhibit a sustained rise in blood pressure, the development of a systolic apical bruit presenting the usual functional signs, and accompanied by some cardiac dilatation. This phase of raised blood pressure is sometimes present during convalescence even from acute rheumatism, and its possibility must always be borne in mind when judging of the nature of a systolic cardiac bruit in children after pyrexia.

The child is far more unstable in its circulatory equilibrium than an adult, and the heart muscle just recovering from the damage of pyrexia is in no case able to sustain the increased work that a slight hyperpæsis involves. A rise of 10 or 20 mm. Hg, which is often to be observed, makes a far deeper impression than in an adult and can be the cause of the cardiac condition. My contention is proved by the fact that as soon as the blood pressure falls the cardiac sounds become normal, in the absence of an organic endocarditis.

The normal blood pressure in childhood has been very little studied in this country. I find a record of 3,000 repeated observations by Jondson and Nicholson¹ in America. The standard of systolic pressure they lay down is as follows:

From 3 to 5 years	50-92 mm. Hg.
" 5 to 9 "	" up to 91 "
" 10 to 11 "	" 99 "
" 12 to 13 "	" 103 "
" 14 to 15 "	" 105 "

I have found that children are very susceptible to the action of the nitrites, and I have employed them in the following combination for reducing blood pressure in my cases: Sodium nitrite, liquor trinitrini, and spt. ætheris nitrosi in suitable dosage. In adults these are of no use. Appended are some notes of typical cases.

W. E., female, aged 9, had a mild faucial attack of diphtheria in February, 1916. Increasing tachycardia was observed as convalescence advanced, and she was kept in bed; ten days later, in spite of cardiac tonics, the heart had dilated beyond the nipple line, and a systolic bruit, not conducted, and heard in all postures,

¹ Being abstracts from a paper read before the Bradford Medical

had developed. Blood pressure 110. There was no albumin in the urine. Nitrites were given: Seven days later blood pressure was 95; the bruit and dilatation had gone. Six days later blood pressure was 96, and there was no bruit. The improvement in the heart did not occur until the blood pressure was lowered.

W. B., male, aged 5, had scarlet fever in June, 1919. There was cardiac dilatation on the eleventh day, with suspicion of an apical systolic bruit. On the twelfth day blood pressure was 100, and on the thirteenth 105. Nitrites were given; on the fifteenth day blood pressure 75, sounds clear, apex beat in the nipple line. On the twenty-fifth day blood pressure was 90, sounds clear; there was no albumin in the urine throughout. He was a highly strung child of a very neurotic mother.

S. D., male, aged 12, had fibrositis with pyrexia in February, 1916. He was the only child of neurotic parents. He had a sudden attack of severe pain in the back, with tenderness to the left of the spine in the lower dorsal region. His temperature was 100°, but was quickly controlled by salicylates. After seven days the heart was rapid and dilated considerably; the sounds were not clear, but he had no bruit. Seven days later there was no improvement; though he was kept in bed; a systolic apical bruit had developed; blood pressure 140. He was given the nitrite mixture, and after three days blood pressure was 120; bruit doubtful. For the next two days nitrites were not taken because of indigestion, and the boy was allowed up without my orders. I found the blood pressure again at 140, with dilatation and bruit more marked. After another three days' treatment the blood pressure was 115, with bruit much fainter. Ultimately he became quite well.

H. B., male, aged 7, had acute chorea in December, 1920. On the 26th the movements were very violent. Temperature 101°; blood pressure 103; there was a systolic bruit at the apex. The bruit and increased blood pressure persisted after the acute phase had passed. On February 1st he was able to walk, and I thought it safe to give nitrites. Blood pressure on February 1st was 105. The bruit was heard both standing and sitting, but was not transmitted to the back; it was intensified on lying down. On February 7th, after nitrites had been given for one week, blood pressure was 95; no bruit was heard in any position.

My conclusions, as a result of this experience, are as follows:

1. To take regular blood pressure observations in all cases of "impure" heart sounds after fever.
2. A rise in blood pressure, usually after, but sometimes during, the acute stage of an infection in children shows that a want of control of the arterial system is developing, and explains a functional bruit when it occurs.
3. If the heart condition in children is relieved by lowering the blood pressure, rest in bed can be dispensed with after sufficient rest has been taken to ensure that the heart muscle has repaired the temporary damage of the pyrexia.

To explain these cases is difficult. Three factors at least must be considered:

1. The patient's temperament. It is particularly the "nervy" children who suffer this disability. The neurotic element is a large one in modern etiology. Cannon² has proved experimentally that the suprarenal secretion is much increased in emotional stresses, such as fear and pain.
2. The action of the toxin upon—
 - (a) The arteries. Toxins are universally credited with a depressor action on the musculature of heart and arteries. I do not wish to question this. My cases are a fairly common exception to the rule that the blood pressure is lowered during an infection. It must not be forgotten, as pointed out by Albutt, that the same causes may operate to produce hyperpæsis in childhood as in adult life. These may be more active after a pyrexia. But this does not disprove my main contention, that the heart condition improves *pari passu* with lowering the blood pressure.
 - (b) The endocrine system. It is not unreasonable to assert that its delicate balance can be temporarily at fault during the toxæmia of childhood's illnesses, and that transient degenerative changes are present in these glands during a fever. It is quite possible, too, that the toxin may exhaust the sympathetic nervous system which controls them. The frequent presence of a compensated acidosis in these cases will, I hazard, be explained in the same way.

The condition thus described is on all-fours with the common "D.A.H." of the soldier. The very name is a glaring example of hasty and slipshod thinking, focusing the attention on the heart instead of on the circulation as a whole. Derangement of blood-pressure control is the correct diagnosis; the heart is only involved in so far as it is over-worked to maintain an efficient circulation. Earlier symptoms, suggesting hyperthyroidism, were common in these cases. In 1921 this phase has passed, and a raised blood pressure is often the only genuine sign of derangement that can be found, suggesting hyperadrenalism. The soldier was taken from sedentary life and drilled to dropping point for some months; he lived for some years on poisonous "dixie" tea and eternal stews, smoked endless cigarettes, suffered fear, lack of sleep, and usually several distinct pyrexias of known or unknown origin. It is no wonder that blood-pressure control broke down, and that when the vicious circle has been

confirmed it takes years to undo by reorganizing the endocrine system and building up the sympathetic nervous system which has become exhausted.

A CLINICAL TEST FOR THE PRESENCE OF CELLULAR ELEMENTS IN THE URINE.

BY

T. H. C. BENIANS, F.R.C.S.,

PATHOLOGIST TO THE PRINCE OF WALES'S GENERAL HOSPITAL, TOTTENHAM, LONDON.

THE object of publishing this note is to put into the hands of the medical practitioner or the nurse a simple means of ascertaining the presence or absence of pus, blood, or bacteria in the urine. The principle of the test is not new, but I have not seen it in standard works on clinical pathology, and from extended observations it seems to me that it should have a useful place in clinical work. This method will frequently reveal pathological conditions in the urinary system where none had been suspected, since it has a wider scope and a much greater delicacy than the clinical methods ordinarily in use in general practice; where a centrifuge and microscope are often not available. If the presence of cellular elements in the urine is shown by this test a further specimen must then be submitted to microscopical examination to ascertain their nature. If the test is negative it can, with a few rare exceptions, be stated that in this respect no further examination is required.

Cellular elements are not normally present in a freshly passed urine, if we except an occasional epithelial cell. If cells are present they may be either bacteria, or cells derived from the body. These latter may be casts from the kidney tubules, or epithelium derived from the urinary tract; or they may be either red or white blood cells, the latter almost invariably polymorphonuclear leucocytes.

Nature of the Reaction.—The test is made to ascertain the presence of peroxidic splitting enzymes in the urine. These enzymes have the power of setting free oxygen from hydrogen peroxide, and the reaction in a fluid medium gives rise to the ebullition of gas bubbles. In addition to enzymes certain other bodies have the power of setting free the oxygen, but for our present purpose haemoglobin is the only one that need concern us. If hydrogen peroxide is added to normal sterile urine no effervescence occurs even after a considerable time has elapsed. It follows that if the addition of the peroxide leads to effervescence we may take it that some abnormal element is present in the urine.

Source of the Enzymes.—These enzymes are present in pus cells or leucocytes in large amount, and these, therefore, give a very free reaction. The enzymes are said not to be present in lymphocytes, but in any case these cells are rarely present, alone at any rate, in urine. Epithelial squames give little reaction, unless heavily infected with bacteria, but the deeper epithelial cells react more freely. Tubo casts may react vigorously. Red blood cells give the reaction on account of their haemoglobin. Of the albuminous fluids fresh blood serum gives an active reaction, probably on account of some blood cells remaining in suspension in it, since other albuminous fluids such as hydrocele and ascitic are inert. The slight reaction usually obtained from an albumin-containing urine is probably due to the presence of casts and a few blood and pus cells such as are usually present in such conditions.

Bacteria.—In an investigation of the various bacteria isolated in the course of routine laboratory work for a considerable period I found that practically all of the bacteria, with the exception of the streptococcal group (which includes the pneumococcus), gave active ebullition with hydrogen peroxide when the cultures were treated directly with it. At the same time it was noted, when bacteria were grown on sugar-containing media (which they fermented with the production of acid), that they were liable to give a negative reaction. This point has to be considered in dealing with very acid urines, since the peroxidic-splitting enzymes only act well in neutral or alkaline media.

Minimal Amounts Giving the Test.—These were ascertained experimentally, using normal urine as a basis and adding the foreign substances in appropriate quantities. The

sensitivity of the peroxide test in the case of blood and pus was compared with the guaiacum reaction. It was found that the peroxide test was positive with about one-twentieth the amount of pus that would just give the guaiacum reaction (using ordinary tincture of guaiacum). The guaiacum test was positive only where there was sufficient pus in the urine to cause a definite turbidity; but the peroxide test gave a positive reaction where no trace of foreign matter could be seen.

With blood the peroxide test was positive with about 300,000 red corpuscles per cubic centimetre of urine, the guaiacum and ozonic ether failing at anything below 1,250,000. To the naked eye the former amount could not be seen in the urine. In the case of bacteria the presence of the staphylococcus was demonstrable in as small numbers as 200 million per cubic centimetre, which number was not obvious to the naked eye except by very careful comparison with a control.

Similar results were obtained with *B. coli* and *B. paratyphosus* B.

Technique of the Test.—If the urine is strongly acid or alkaline to litmus it should first be neutralized by the addition of a few drops of dilute alkali or acid. The peroxide should be fairly fresh, not less than 20 volumes in strength—40 volumes is better—and not too acid in reaction. I have obtained by far the best results with the neutral 100 per cent. fluid issued by Merck's under the name of "perhydrol," as with this concentrated solution only a few drops are needed for the test.

Take about a third of a test tube of urine and add about a quarter of the amount of the 20 volumes peroxide solution to it. Stand the tube in a rack, not in direct sunlight, or spontaneous evolution will take place. In a strongly positive reaction bubbles start to rise immediately and form a permanent layer of foam at the top of the fluid. If the reaction is only faintly positive bubbles will gradually rise and form a thin layer on the top; this may take from fifteen to twenty minutes or longer if the urine is acid. A few bubbles lying on the meniscus are made more evident by gently rocking the tube to throw them down into the fluid.

All degrees of effervescence may occur between the two described. In a normal urine one or two bubbles may rise immediately after the addition of the peroxide, especially if the urine is warm, but there is no steady evolution of gas or formation of a layer of foam.

Sources of Fallacy in the Test.—(1) Accidental contamination of the specimen with bacteria is a frequent source of error since the ordinary specimen glass is as a rule grossly contaminated with bacteria. Moreover, in non-catheter specimens, if several hours old, there is certain to be a good deal of bacterial growth which would give a positive reaction. It follows that the specimen must be collected in a quite clean vessel, and unless a carefully taken catheter specimen is available the test should be carried out shortly after the urine is passed. In the case of females a catheter specimen though not imperative is advisable on account of the cellular and bacterial debris that may be present. (2) The ordinary peroxide solutions are likely to be definitely acid, and this may lead to error in several ways. If an unnecessarily large amount of the reagent is added the action of the enzymes will be inhibited. More than this, if carbonates are present, the acid will act on them and lead to effervescence and so to a faulty diagnosis.

Summary.

Peroxide splitting enzymes are derived from most cellular elements. Hydrogen peroxide is also decomposed by haemoglobin from red blood cells. Cellular elements are not present in normal urine; in pathological urines those most often present are red blood cells, pus cells, and bacteria. In nearly all cases the presence of these bodies or their derivatives can be shown by this test, even when present in amount very much smaller than can be detected by the clinical tests commonly in use. The test, however, does not differentiate between one form of cellular element and another; it shows with a very small percentage of error whether abnormal bodies are or are not present, and whether or not further investigation is needed.

The reaction is negative with the various crystalline deposits (with the already noted exception of carbonates).

NOVEMBER 23RD was set apart by the municipal authorities of Berlin for the extermination of rats. The owners of property in the city were ordered under a penalty to distribute on that day in appropriate places upon their property effective rat poison to the value of fifty marks.

Memoranda :

MEDICAL, SURGICAL, OBSTETRICAL.

FRACTURE OF THE END PHALANX OF A FINGER, WITH RUPTURE OF THE COMMON EXTENSOR TENDON.

(With Special Plate.)

THERE is a device, known to many, for opening a clenched fist. It consists in forcibly approximating the tip of a finger to the first interphalangeal joint (by flexion). I have had a case recently of this kind. The *fons et origo malorum* was a coin in the closed hand of one person which another individual was desirous of releasing.

The aggressor in the struggle began by forcing the tip of the little finger towards the first interphalangeal joint (flexion). The result of this procedure was a swelling in the distal interphalangeal joint, which did not subside in a reasonable time. I accordingly made a radiogram of the joint. This showed that a portion of the bony substance of the dorsal proximal part of the distal phalanx was detached, and the result was incapacity to extend fully the end phalanx.

Treatment, which consisted of hyperextension for a few weeks, was quite successful, power to extend the phalanx fully being completely restored. The illustrations are radiograms taken before and after treatment. (See Special Plate.)

I have found an injury due to similar kinds of violence described under the name of "drop finger" or "mallet finger," but I think the interest in this case consists in the detachment of bone, which is shown in the radiogram, and which I am unable to find previously described.

I have to thank Mr. Hedley Marsh for helpful criticism.

Macclesfield.

JOHN N. LAIRD, M.D.

TORN SPLENIC ARTERY—SPLENECTOMY.

T. G. was admitted into the North Lonsdale Hospital in a state of collapse; as a result of an accident, on April 26th, 1921. He had fallen into the hold of a ship, first 30 feet on to a plank, then bouncing off the plank and falling another 10 feet.

On examination there was obviously acute abdominal trouble, with dullness in the left flank. I at once opened the abdomen and found blood in the peritoneal cavity, the splenic ligaments were torn away with the splenic artery, the artery was torn at the exact junction with the spleen as if shaved off, but the spleen itself was practically undamaged.

I removed the spleen, ligatured the splenic artery, closed the abdominal wound, and the patient left the hospital on June 20th.

The accident was remarkable inasmuch as there was no other bodily injury at all. I attribute the peculiar separation of the artery to the sudden break in the fall when at 30 feet he bounced off the plank and thus snapped the artery.

On November 23rd I had a blood film examined at the Yorkshire Pathological Society, the report of which was that the red corpuscles showed no abnormality, and were almost uniform in size and shape, and that the leucocytes seemed to bear the normal proportion to the red corpuscles. On the same date the patient seemed to be in very good health, normal weight 9 st. 4 lb., height 5 ft. 4 in., and apparently not missing his spleen in any way.

JOHN ARTHUR REED, O.B.E., M.B., Ch.B.,
Honorary Surgeon, North Lonsdale Hospital,
Barrow-in-Furness.

AN OPERATION FOR THE RELIEF OF ASCITES, FOLLOWING CIRRHOSIS OF LIVER.

A MALE Hindn, aged 35, about twenty-five years ago had an attack of malaria lasting nearly one year. About ten months ago he suffered again from malaria, and since that time he noticed gradual swelling of the hypogastric region. This swelling increased, gradually extending to the whole abdomen. He had severe attacks of epistaxis; soon after his legs also commenced to swell. The patient is an inhabitant of a village about sixty miles from Kurduwadi, Deccan, India, the condition of which is insanitary.

When he consulted me he complained of pain after food, he had dyspnoea while walking, and suffered from slight insomnia. On examination the chest was emphysematous

and the heart pushed upwards, due to fluid in the abdomen. The pulse was feeble. There was oedema of the face and lower extremities, and the abdomen was distended evenly; on palpation fluid and thrill were present. The abdomen was 40 inches in circumference, the liver was contracted, and the spleen enlarged. He was passing little urine, and that was high coloured, but with no albumin or sugar.

Injections of quinine bihydrochloride, 5 grains, were administered every third day; six injections were given in all, but there was no improvement. The abdomen was tapped three times, about every fifteen days, and 100 oz. of fluid were removed each time.

Operation.

The patient was tapped one evening previous to operation, and 100 oz. of fluid removed, but as the pulse was weak and feeble, operation was not performed on the same day as the tapping. Under chloroform a semicircular skin incision, about 3½ to 4 inches long, was made midway between the umbilicus and left iliac crest, with the base downwards. A semicircular flap was turned down, the external oblique was incised for 1½ inches parallel to its fibres at the base of the flap, and the internal oblique was incised for 1½ inches along its fibres. The peritoneum was exposed and a puncture about the size of a quill carefully made, when an amount of ascitic fluid came away. A purse-string suture of catgut was put round the puncture through the internal oblique muscle, the head of the "stud," described below, was introduced into the peritoneal cavity, with the base of the stud resting on the internal oblique muscle. The catgut suture was tightened round the neck of

Plan and section of "stud" made of silver. The principle of this stud is to drain the ascitic fluid accumulating in the peritoneal cavity through the opening into the surrounding tissues.

the "stud." All haemorrhage was stopped by artery forceps or suture. The external oblique came together by natural apposition, and was sutured with catgut. The semicircular skin incision was closed by silver suture and the wound dressed with double cyanide gauze.

On the second day after operation the patient got up and walked, against advice; in consequence there was a serous discharge of fluid from the wound. A pressure bandage was applied for a few days until the skin incision had well healed. There was no complication of fever. On the third day the skin round the wound was lightly inflamed, due to application of tinct. iodi.

Within twenty-four hours of the operation the oedema of the body went down, and the abdomen was flaccid. The edema of the legs diminished on the third day, and the pedal oedema was greatly lessened. There was some oedema of eyelids and foot on the fifth day. The sutures were removed on the sixth day, and after twelve days the wound was healed. The patient left the hospital and returned to his own country about the sixteenth day, as he stated he was well, and did not complain any further of ascites. On the day he left there was still some fluid in the abdomen, but it did not cause discomfort.

JAMES L. BOCARRO, F.R.C.S.I., D.P.H.Camb.,
Chief Medical Officer, Barsi Light Railway
Hospital,
Kurdawadi, Deccan, India.

THE CLASSIFICATION OF SQUINT.

An interesting communication on squint by Lieut.-Colonel Smith in a recent number of the BRITISH MEDICAL JOURNAL recalled to me the classification of cases of squint which I was in the habit of giving to the medical students who attended my classes.

My general definition of squint is as follows: "When the axes of vision do not intersect at the point of fixation then there is squint." I divided the affection into two groups—namely, (a) mechanical squints, (b) functional squints. In the first the axes of vision are prevented from intersecting by such conditions as paralysis or paresis of one or more muscles of one or both eyes. To this class also belong those cases in which the presence of an orbital tumour prevents movement and thus interferes with the intersection of the axes at the point of fixation.

Functional squints are those in which there is no mechanical obstruction to movement, but where the defect is due to a difficulty of fusion. The commonest form of this variety is concomitant convergent strabismus. Under this head are also to be classed those cases in which there is marked defective vision in one eye, so that the intuitive perception of the third dimension of space is impossible. In general the squinting eye, when the condition is due to disease in one, diverges—that is, assumes the usual anatomical position of rest.

The exact classification of heterophorias is perhaps a little doubtful, and may be considered from two points of view. On

the one hand, they may be regarded as due to deficiency in the nerve energy supplied to one or more of the extrinsic muscles of one or both eyes. If that view be taken they must be looked upon as cases of muscular paresis. On the other hand, if they are regarded as due to defective fusion centre, then they may more properly be considered as belonging to the second group.

Glasgow.

A. FREELAND FERGUS, M.D., LL.D.

Reports of Societies.

HYPERTHYROIDISM IN FUNCTIONAL MENORRHAGIA.

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, held on January 5th, with the President, Professor HENRY BRIGGS, in the chair, Mr. ALFRED W. BOURNE read a paper on hyperthyroidism in functional menorrhagia. There is, he said, a large class of women suffering from menorrhagia in whom no local signs of disease can be discovered in the pelvis. Clinical examination and curetting of the uterus both fail to reveal abnormality, and ordinary methods of treatment by drugs and organic extracts are useless in arresting the excessive haemorrhage. A series of cases of this type has been examined with a view to hyperthyroidism as a cause, and defining a menorrhagia as due to hyperthyroidism.

Clinical examination of the patients was first made in order to detect those physical signs and symptoms usually associated with hyperthyroidism. The most prominent of these were loss of weight and nervous instability. Others less constantly present were increased pulse rate, slight tremors, and a tendency to sweat easily. Enlargement of the thyroid was occasionally present, but more often normal in appearance. Exophthalmos was only present in one case. The two pieces of evidence supporting the view of hyperthyroidism as the causal factor were, first, the increased basal metabolism, as determined in all cases by Dr. C. M. Wilson, and, secondly, the reaction of both the basal metabolic rate and the symptom of menorrhagia to the application of x-rays to the thyroid gland.

Measurement of the basal metabolic rate (B.M.R.) differentiated the patients into two groups: (a) Those at or about the age of puberty (six cases only), who showed a normal or depressed B.M.R. in five out of the six, in spite of considerable thyroid enlargement in some of them; and (b) those patients who were sexually mature. All these cases (14 in all) showed a raised B.M.R. of about +20 per cent., the lowest being +14 per cent., and the highest +46 per cent. Three were married, with menorrhagia dating from the last confinement. The uterus in these patients was distinctly smaller than normal. The suggestion was made that the normal hyperthyroidism of pregnancy had persisted with the production of a functional menorrhagia.

The second piece of evidence was the effect of x-ray application to the thyroid gland, carried out by Dr. G. Harrison Orton. The second group, sexually mature, reacted after a few doses of x-rays to the extent that eight out of ten had the B.M.R. reduced to within normal limits (—10 per cent. to +10 per cent.), together with the return of normal menstruation, while the two patients whose B.M.R. persisted at a high figure showed no menstrual improvement. In cases where a relapse occurred the B.M.R. rose *pari passu* with the return of menorrhagia. The group at or about the age of puberty examined after x-ray application were too few, but of the four three had shown no improvement.

Dr. HARRISON ORTON said that all the cases described by Dr. Bourne, with one or two exceptions, had been treated in exactly the same manner, the procedure being as follows: a dose of 1/2 B or 5 X was given once a week for three doses, the filter being 1 mm. of aluminium and four layers of wash leather. After this, doses of 4/5 B were given once in three weeks through a filter of 3½ mm. of aluminium and wash leather as before; rays should be hard, not less than 9-10 on the Baner qualimeter. The average number of doses was about eight. It was important that no erythema of the skin be produced, as this was likely to lead to the formation of telangiectasis in the skin, which might become very unsightly. In one of Dr. Bourne's cases, and in another case of Graves's disease, he had seen a tendency to myxoedema produced after eight such exposures, so he thought it advisable to have the basal

metabolism tested again after six exposures; on the other hand, some cases had had considerably more than eight exposures without improvement, so that the amount required seemed to be very variable. He thought it should be remembered, too, that cases of Graves's disease, which had had no x-ray exposures at all, had been reported, in which myxoedema developed subsequently. He had no doubt that the estimation of the basal metabolism would eventually lead to a much more accurate dosage being determined.

Mr. BECKWITH WHITEHOUSE read a short communication on salpingotomy *versus* salpingectomy in the treatment of tubal gestation. He pointed out that in all cases of tubal mole the attachment of the mole to the tube is small, and that the rest of the mole can be easily detached from the wall. These considerations suggested the possibility of preserving the tube after removal of the mole from the tube *in situ*. In a series of ten cases he incised the tube, removed the mole, and controlled the bleeding by suture, and then removed the tube for examination in detail for evidence of inflammatory change. In all the tissues appeared normal. Since then he had removed the gestation and sutured the tube in five cases, with apparently satisfactory results. He thought probably removal of the tube in cases of rupture was the better procedure, but in cases of tubal mole and tubal abortion salpingotomy appeared to be worthy of a trial.

Mr. JONAS B. HUNTER made a short communication and showed microscope slides from a case of general vascular carcinoma. The patient was a woman of 35, who had had six weeks' history of rectal and vaginal pain before admission to University College Hospital under Dr. Blacker. There was no history of bleeding, but there had been rapid wasting. Examination revealed infiltration of the vaginal walls down to the urinary meatus, the cervix appeared nodular, bleeding slightly on examination, but there was no ulceration. The only treatment thought likely to influence the condition was radium, and although there was apparently considerable improvement under treatment the patient remained in an exhausted condition and died. On *post-mortem* examination there was found a deposit of growth on the chordan tendineae of the mitral valve. The pleura, lungs, spleen and liver contained deposits of growth. Douglas's pouch was closed by adhesions in which growth was present. Microscopically, all the organs examined showed the presence of growth, and in the broad ligaments was widespread growth; some of the vessels were blocked by growth, some had central cores of growth with circulating red cells surrounding them. Mr. Hunter thought the peculiar distribution of the growth throughout the vessels of the body justified the term of a general vascular carcinoma.

Mr. BECKWITH WHITEHOUSE showed a specimen of tubal lithopaction, the patient being a woman of 45, who had had two children. Fifteen years before being seen by Mr. Whitehouse she had had what was described as a very bad miscarriage followed by an acute illness, which had kept her in bed practically for three months. There had been no subsequent pregnancy, and the periods became regular, although profuse. Attacks of severe cystitis occurred at intervals for several years, and the diagnosis for renal calculus had been made five years before Mr. Whitehouse was consulted. The specimen showed the appearances of a typical lithopaction corresponding to a gestation of about three months; the cranial bones, vertebrae, scapula, pelvic girdle, and certain digits were all recognizable on the surface. The patient made a good recovery, but five months later died from double pyonephrosis.

TREATMENT OF PSYCHOSES.

In the Section of Psychiatry of the Royal Society of Medicine, on January 10th, with Dr. R. PRATER SMITH in the chair, Dr. R. G. ROWS gave an address on "Modern methods in the treatment of psychoses."

Dr. ROWS said that there did not seem to be any basis for a scientific distinction between the psychoneuroses and the psychoses, although such a distinction might be useful from a clinical or descriptive standpoint. If it was intended to speak of an organic basis for psychoses, they must be considered from the earliest moment of their appearance and must not depend upon examinations which had been made a number of years after the trouble began, for in later stages there might be very definite changes in the central nervous system. From the point of view of recoverability, there was

no distinction between the two things at all; both were recoverable if treatment was applied in the early stages, and were difficult if treatment was long delayed. All mental illnesses existed for a long time before they were obvious to those associating with the victim. By mental illness Dr. ROWS meant a condition in which there was a disturbance of the ordinary mental activities, such as proceeding, thinking, feeling, judging, giving attention and assessing values. The patient himself was the first to recognize an abnormality. Sometimes there was definite disturbance during the night, but apparent normality in the daytime, until later the abnormality extended to relationships in the world.

Freud counselled that symptoms should be regarded merely as directing posts indicating lines of investigation, and this investigation would show the cause of the symptoms manifested. He himself found symptoms to be of extraordinarily little value in understanding a case. If the wildest deliriums were analysed some experience would be found in the earlier life of the patient to account for the form which the disorder assumed. Once the mental illness was established, with a dominant emotional tendency, every incident of the past which had been accompanied by a similar emotional state added its weight to the disturbing influence. His contention was that the emotion in all such cases was a normal reaction to the stimuli which caused the mental disturbance. The sequence of stimulus, association, inhibition, and reaction, although worked out possibly in an exaggerated form, was the product of the old mechanisms; a new mechanism was introduced into the evolution of the psychosis. The ordinary symptoms relied upon for the diagnosis of the various types of mental disorder were as a rule secondary developments. Mental illness was present before the delusion or the hallucination arose. As time went on, the repetition of the stimulus or the recollection of the stimulus brought about a habit of thought from which it was exceedingly difficult for the patient to escape. The most trifling cause was sufficient to set in motion the memory mechanism, and the patient thereupon fell into a state of terror or whatever the emotional manifestation might be.

Dr. ROWS went on to say that it was impossible to understand mental illness by considering the psychic side alone. Every experience which crossed the threshold of consciousness had three results: an intellectual perception of the fact, an emotional reaction, and a physical reaction. The emotion of acute fear, for example, was associated with a disturbance of practically every organ of the body, quite as the normal result of the stimulus. Many of the symptoms of organic reactions in patients were simply physical changes connected with the expression of the emotions, and did not indicate any definite physical disease; they were natural consequences of the emotional state in which the patient found himself. Mental illness was not merely the result of a change in the nervous system; if the mental processes were to be understood the organism must be taken as a whole, or, at least, if attention was concentrated on the nervous system, its normal reactions must be very carefully worked out.

In the course of a brief discussion the CHAIRMAN expressed the opinion that Dr. ROWS had been too sweeping in his suggestion that symptoms were recognized by the patient long before anybody else recognized them; in a good many cases the patient did not recognize the position at all. Dr. W. H. B. STODDART believed that Dr. ROWS's method of approach was the correct one, although he thought it would be a long time before it came into general employment in the asylums. It was necessary to go back to a very early age to find the influences which prepared the soil for the subsequent breakdown.

Dr. H. CRICHTON MILLER said that the contention that in psychoses we constantly saw the normal reactions of the mind was rather discounted by the large number of mechanisms which were recognized as being normal in childhood but abnormal in adult life. It might be perfectly normal for the child to indulge in phantasy, but if this process continued or recurred in the adult a psychosis was apt to develop. To say that this regression to a puerile experience was due to a normal mechanism was only true in a limited sense; it was a regression, not a progressive reaction to experience, and therefore was abnormal.

Dr. ROWS, in reply, disagreed with Dr. Crichton Miller, and claimed that the various emotions, such as remorse and fear, were normal reactions of the adult as well as of the child. They were part of a defensive mechanism which certainly appeared first in childhood, but remained with the individual throughout his life.

MATERNAL MORTALITY.

THE fourth meeting for the session of the Ulster Medical Society was held on January 12th, the chair being occupied by the President, Dr. ROBERT HALL.

Professor C. G. LOWRY read a paper entitled "Maternal mortality: a retrospect." Child-bearing, he said, was no doubt a physiological process, but it was not for the woman's own benefit, as other physiological processes were, such as eating, breathing, urination, etc.; it was for the benefit of the nation. It was incumbent, therefore, on the nation to see that the process was as safe as science could render it. Mortality had fallen in surgical work, and sepsis had practically been banished; it had also decreased in such affections which threatened the human race as tuberculosis, but the mortality from childbirth was still too high and had not fallen in at all the same proportion. In Ireland in 1920, 550 deaths had occurred attributable to child bearing, and of these 46 per cent. were due to sepsis. Deaths per 1,000 births in England and Wales had even increased; they were 4.81 in 1908 and 7.6 in 1918; this latter figure was probably due to influenza. In Ireland the mortality rate per 1,000 had varied from 5.62 in 1914 to 6.26 in 1920. No corresponding diminution followed the introduction of antiseptics or aseptics; it was 5.5 per 1,000 in 1850, 4.6 in 1860, 4.9 in 1870, 4.0 in 1880, 5.7 in 1892, 4.4 in 1902, and 4.9 in 1912. No diminution was found in the United States of America, nor in fifteen other countries. In Scotland it had risen from 5.0 in 1870 to 6.1 in 1915. England had a present average of 1 maternal death for every 250 births, Ireland 1 for every 191, Wales 1 for every 179, and Scotland 1 for every 175. Mortality from puerperal sepsis in England was 2.56 per 1,000 births in 1881-90 and 1.39 in 1911-14; in Wales, 3.11 and 1.67 in same periods; in Scotland, 2.42 and 1.44; in Ireland, 2.83 and 2.01. The death rate from accidents and diseases had altered very little.

Professor Lowry then gave a graphic account of the Vienna school in its earlier days and of the struggles of Semmelweis. He pointed out that instead of obstetrics being indebted to surgery for its rules and borrowing guidance from it, in a belated fashion, if Semmelweis had received the support of an educated and unenvious profession obstetrics would have led the way to aseptics fifty years before surgery had learnt its lesson. He then laid down the lines of advance in the future, the use of the ante-natal clinic, which was now in full work at their maternity hospital, the necessity of endeavouring to prevent and anticipate trouble, such as eclampsia (a condition more easily prevented than cured), the advisability of having cottage maternity hospitals in every district, and other recommendations. Anaesthetics and antiseptics had proved very doubtful benefactors in midwifery; they encouraged interference when interference was harmful. The speaker paid a grateful tribute to the work of Mr. Victor Bonney, and for his inspiring help in this subject.

Dr. W. R. MACKENZIE read a note on "Rupture of Caesarean section scar in subsequent pregnancy," and showed the specimen of the uterus which he had successfully removed. A woman, aged 28, healthy, was delivered by Caesarean section in 1918 for contracted pelvis by Mr. John Campbell, and again in 1920; in her third pregnancy labour began on September 20th, 1921, and after eighteen hours she was operated on by Dr. Mackenzie. She had no sign of collapse or of internal haemorrhage; he found the dead foetus and placenta free in the abdominal cavity, and a large rupture, extending the whole length of the previous scars, in the anterior surface of the uterus; the uterus was removed by subtotal hysterectomy, and the patient made an uninterrupted recovery. Dr. Hall of Monaghan, who had assisted in the previous operations, assisted also in this one.

Drs. STOREY, TRIMBLE, RENTOUL, GAUSSEN, SHAW, THOMAS HOUSTON, offered criticisms and remarks on both papers, and Professor Lowry and Dr. Mackenzie replied.

ACUTE INTESTINAL OBSTRUCTION.

A MEETING of the Manchester Pathological Society was held on December 8th, 1921, with the President, Mr. J. Howson RAY, in the chair, when Mr. D. P. D. WILKIE of Edinburgh read a paper on acute intestinal obstruction. Mr. Wilkie first insisted on the distinction which must be drawn between simple obstruction of the lumen of the gut, and obstruction plus interference with the blood supply of a segment. He passed on to consider the question from the standpoint of

the factors causing death in the three main types of intestinal obstruction—by (1) simple obstruction of the lumen in its continuity, (2) closed-loop obstruction, and (3) strangulation. In the first variety a clear distinction could be drawn between high obstruction with copious vomiting and an early fatal issue, and low obstruction with slowly increasing toxæmia. From experimental data it appeared that the absorption of toxins was a relatively slow process through unbroken intestinal mucosa, and that emptying of the bowel was necessary only in late cases. The toxin probably belonged to the proteose group, and retention of it in the upper jejunum was associated with most danger. In the closed-loop obstruction, most typically seen in acute obstruction of the appendix, toxæmic symptoms depended on the presence of faecal matter within the closed loop. Putrefactive changes in the retained faecal matter gave rise to profound toxæmia and to gangrene of the wall of the loop. When no faecal matter was present in the loop toxæmia was absent, and a mucocle or at most a slowly forming empyema of the loop resulted. In cases of strangulation shock was the primary and dominant factor, and death might result before toxæmia was demonstrable. The essentials of treatment consisted in prompt operative interference, minimizing shock by the free use of morphine, subcutaneous saline, and gas and oxygen anaesthesia. Rapid and conservative operating was necessary, and post-operative administration of saline subcutaneously, gastric lavage, and pituitrin and enemata were further measures which should be taken to ensure an early evacuation of the toxic content.

The lecture was illustrated by means of lantern slides showing charts, photographs of experiments, and water-colour drawings of specimens.

PRE-ANAESTHETIC INTOXICATION.

A MEETING of the Scottish Society of Anaesthetists was held at Glasgow on November 26th, 1921, in the Hall of the Faculty of Physicians and Surgeons, and Dr. J. JOHNSTON, of Aberdeen, the new president, read his inaugural address upon the subject of "Some pre-anaesthetic intoxications." The types of intoxication discussed included the various drug habits, alcoholism being considered at some length as being fairly typical and most likely to give trouble to the anaesthetist. The pathology was briefly outlined, and the possibilities of preliminary curative treatment were reviewed, particularly as to the reduction of acidosis; the value of the judicious use of pre-operative hypnotics was emphasized. The intractability of the alcoholic patient under general anaesthesia was regarded as being due mainly to defective oxygenation; the chief danger was paralysis of the medullary centres and heart failure. The choice of anaesthetic was discussed, methods combining the administration of oxygen with the various mixtures of ether and chloroform being preferred in most cases, the chloroform to be used as sparingly as possible. The danger of post-anaesthetic acidosis was noted and its prevention discussed. Variations from this type in the case of other drug habits, such as morphiism and cocaineism, were mentioned, and the question was raised as to the possibility of anaesthetic troubles due to the habitual use of such drugs as aspirin. The late effects of shell-gas poisoning as affecting anaesthesia were also shortly reviewed.

Dr. JOHN ANNENSON, Pathologist, Victoria Infirmary, Glasgow, submitted to the society the clinical facts of the cases of death during the administration of anaesthetics which had taken place in Glasgow during the past thirteen years. Statistics of 417 cases were presented, showing the sex, age, and condition of the patient, the anaesthetic used and time of administration, the surgical operation or disease for which the anaesthetic was administered, and the opinion as to the nature of death. The paper was freely discussed by the members present.

CELLULOID SPLINTS.

AT a meeting of the London Association of the Medical Women's Federation on January 10th, at the Elizabeth Garrett Anderson Hospital, with Mrs. FLEMING in the chair, Dr. CHARLOTTE BROWN gave a description of the ambulatory treatment of tuberculous disease of bones and joints, and showed splints used by her at the High Beech Hospital, which has been established in the last two years by the Essex County Council for the treatment of cases of non-pulmonary tuberculosis. The object of her demonstration was to emphasize the many advantages of celluloid splints made on the Alton pattern for cases of bone disease where

activity had been arrested and where a limited amount of protected movement was beneficial. The celluloid splints were made from a plaster cast taken from the patient, so that they could be most accurately fitted. They were extremely light, very durable, and could be washed as easily as a dinner plate. They were not affected by the heat of the body, and the danger of the inflammability of celluloid had been overcome by mixing calcium chloride with the celluloid solution. Dr. Brown described the making of a splint in minute detail, and explained how easy this was. The time needed for the drying of the thirty or more layers of celluloid which had to be painted on was probably the reason why such splints were expensive to buy; when made at home the painting on of the celluloid took very little time. She added that light splints, such as she showed, could probably be employed with advantage for other than tuberculous conditions. They could be used for cases of infantile paralysis with great benefit, since the correction of malposition with the allowing of a certain amount of muscular action was very advantageous.

THE annual meeting of the Harveian Society was held at 11, Chandos Street on January 12th. The formal business having been completed, the retiring President, Dr. G. de B. TURTLE, delivered his address entitled, "Some points on spasm in the alimentary tract." The thanks of the Society to the retiring President were proposed by Dr. ROOTH and seconded by Professor LANGMEAD, and carried by acclamation. The Society then expressed its hearty approval of the work of the other officers, and Dr. Frankish replied on their behalf. The new President, Sir William Wilcox, K.C.I.E., was then invested and installed in the chair.

Reviews.

SEX RELATIONS AND BIRTH CONTROL.

THE speech on sexual relationships which Lord Dawson of Penn was invited to deliver at the Church Congress at Birmingham last October has been published in a pamphlet entitled *Love—Marriage—Birth Control*.¹ The subject matter, as he says in a foreword he has written for the pamphlet, "aroused widespread interest and some controversy." The reports published at the time, he adds, being condensed, inadequately and in some instances incorrectly set forth the views he championed. It is satisfactory therefore to have an authentic version, and by reading it in its entirety misapprehension may be avoided. We propose here to give an outline of what we understand Lord Dawson's argument to be.

The first part of the speech was devoted to the study of the significance and purport of sex love in a well ordered and Christian community, and provision for its healthy outlet. Sex love, says Lord Dawson, should be the physical expression of a lasting affection, blended so as to form a union of body, mind and spirit. Further, it should be associated with the love of and desire for children. To save time the speaker dealt with the problem of sex love and not with that of child love; and with sex love in relation to marriage and not with illicit intercourse; though he notes that if in any community marriage is difficult or late of attainment an increase of irregular unions inevitably occurs.

Lord Dawson considers that people need more knowledge of the scientific bearings of sex relations, and more clearly defined guidance in their rightful practice. He finds that people talk about instructing the young in these matters when, unfortunately, they are neither clear nor agreed amongst themselves. The Anglican Church, in the Marriage Service, appears, he says, to imply that marriage exists for the purpose of giving people who cannot be continent the best way out; while the Lambeth Conference seemed to condemn sex love as such, and to sanction it only as a means to an end—procreation. To Lord Dawson, on the other hand, the love indicated by the Lambeth Conference is an invertebrate, joyless thing—not worth having. "The churches will never gain the allegiance of the young unless their attitude is more frank, more courageous, and more in accordance with reality." "Romance and deliberate self-control do not, to my mind, rhyme very well together." "If sexual union is a gift of God it is worth learning how to use it." It should be cultivated so as to bring physical satisfaction to both, thus constituting a firm bond between two people and making for

durability of the marriage tie. Passion, Lord Dawson continues, is a worthy possession; most men who are any good are capable of passion. But passion must not be confounded with sensuality. The real and effective restraints to passion are "a loving and sympathetic companionship, the privileges of parenthood, the exacting claims of career, and that civic sense which prompts men to do social service." Therefore Lord Dawson would like to add to the objects of marriage in the Marriage Service the following statement: "The complete realization of the love of this man and this woman, the one for the other."

Passing on to deal with the subject of birth control, the speaker began by pointing out that birth control is here to stay, and that as the Roman Catholic Church with its authority and discipline cannot check it, it is most unlikely that Protestant churches could do so. Absence of birth control means, according to Lord Dawson, late marriage, and late marriage means illicit intercourse with all its baneful consequences. The suggestion that the only birth control justifiable is voluntary abstinence from conjugal relations is dismissed with the statement that "such abstinence would be either ineffective, or, if effective, impracticable and harmful to health and happiness."

In discussing artificial control, Lord Dawson says that it is no more unnatural to control conception by artificial means than to control childbirth by artificial means. The only question is whether these artificial means are for the good or harm of the individual and the community. Contraceptives do harm when they are used to render unions childless or inadequately fruitful. They may do good by limiting the number of children and spreading out their arrival in such a way as to serve their true interests and those of their home. There is no evidence that the use of contraceptives leads to excessive indulgence; by the time and circumstance of their application they involve prudence and control. Lord Dawson appears to favour a family of four born at proper intervals. In the view of other authorities also this is the minimum of children that should be born of every marriage if due allowance is to be made for deaths in infancy and childhood.

The reasons which lead parents to limit the number of their children are sometimes selfish, says Lord Dawson, but more often honourable and cogent. He gives the following: The desire to marry and to rear children well equipped for life's struggle; limited means; the cost of living; burdensome taxation; and, amongst the educated classes, the desire of women to take a part in life and their husbands' careers. Furthermore, Lord Dawson asserts that it must be admitted that baby after baby every year or eighteen months wears and often exhausts a woman's strength. It is at this point that we venture to raise two questions. Is it true, in the first place, that the average woman is exhausted or worn out by having a large family? Secondly, can Lord Dawson's other reasons be distinguished easily from forms of selfishness? Another writer² has given the reasons commonly adduced for restricting the number of births succinctly: "First, economy; second, comfort; third, safety; fourth, race welfare." And this writer has no difficulty in disposing of the first three reasons to his own satisfaction. He is prepared to admit some soundness in the fourth reason; but points out that people who wish to remain with none or with one or two children do not commonly bring this forward in support of their determination. Lord Dawson desires the selection of the times of conception of children so as to give those children a better upbringing rather than selfishly to leave the sequence of offspring to blind chance. The other view is that such selection destroys the spirit of adventure, reduces the incentive to exertion on the part of the father for the maintenance of his family, and is in reality the more selfish course. It is possible that this view receives some corroboration from the state of affairs that has prevailed in France.

We have tried to summarize Lord Dawson's speech in such a way as to avoid misapprehension. And we have expressed no views of our own because the matter seems at present by no means ripe for dogmatic statement. While admiring the courage of Lord Dawson in bringing this subject before such a body as the Church Congress, and inviting discussion of what he considers a vital problem, we are inclined to regret the absence from the speech of exact and definite indication why Lord Dawson advocates the practice of birth control. Is it on the ground of over-population, or for the improvement

² Dr. J. W. Ballantyne's article on Birth Control in *Mothers in Council*, October, 1919.

of the race eugenically; or that more time and care may be spent in the bringing up of the fewer children actually born; or, lastly, is it for the more hedonistic purpose of allowing time for the "complete realization of the love of this man and this woman, the one for the other"?

It is possible, however, that in ventilating the subject before a clerical and lay body, Lord Dawson had in mind an indirect object—namely, to use popular interest in such a manner as to induce the medical profession to come to an opinion upon birth control and the measures to be taken to ensure it. The adoption of birth control as an established principle involves so many social, economic, and even political questions that the medical profession may well hesitate before making any collective pronouncement. It appears to us that for the present it must remain a matter of conscience between the two parties to a marriage in the first place, and secondly, if they seek medical advice, for the judgement of the doctor they may consult. But there are undoubtedly cases in which further pregnancy is undesirable or extremely risky. In such cases the patient or her husband is almost certain to ask for advice. The majority of medical men would probably feel justified in advising contraceptives in such cases; the propriety of birth control under certain conditions is thus conceded. The best and most innocuous method is therefore a subject proper for discussion by a medical society. The recent discussions in our correspondence columns prove that on the question of whether birth control should be favoured as a general practice medical opinion is divided. It is useless to shut our eyes to the fact that it is largely practised among the educated and well-to-do classes, or to the further fact that statistics collected before the war showed that the highest birth rates were recorded in the poorest districts, there being an almost regular fall from the fashionable districts to the slums.

TUBERCULOSIS.

THE seventeenth and eighteenth volumes of the *Traité de Pathologie Médicale et de Thérapeutique Appliquée*³ offer a remarkably complete survey of tuberculosis by a number of distinguished collaborators. The first of the two volumes takes a general view of the tuberculous infection, its etiology, pathological anatomy, and bacteriology. There are also excellent chapters upon treatment of every kind, directed, not against particular localizations and manifestations of the disease, but against tuberculosis regarded in a wide sense as a specific infection. The second of the two volumes deals with the various clinical forms of tuberculosis as it affects the infant, the adolescent, and the adult. The book keeps marvellously to the limits implied in the title of the series—namely, a treatise of medical pathology. It is a topographical voyage of discovery through the human body in search of tuberculous lesions and the signs they give rise to during life. The colour photographs illustrating the morbid anatomy are as good as anything we have seen.

The book is one of reference and is full of information, but the index is not detailed enough to make the information readily accessible. The index treats of generalities; the value of the book really consists in a wealth of minute particularities.

Professor KLEMPERER's book on pulmonary tuberculosis⁴ contains the results of the author's observations during twenty years of hospital and private practice. The post-war increase in pulmonary tuberculosis in the central countries of Europe induced him to think that a summary of modern views on consumption would be useful to medical men, but his book, though carefully written and well arranged, does not contain a great deal that is new to English physicians. Like most observers, he comes to the conclusion that the bovine bacillus plays a relatively small part in the production of pulmonary tuberculosis in man, holding that though it may set up other lesions it rarely attacks the lungs. He believes that the majority of all cases of tuberculosis in man are the outcome of infection contracted in childhood which has lain latent in the lymphatic glands. Two principal portals of entry are open to the bacillus—namely, the re-

spiratory tract and the alimentary canal; Klemperer thinks they divide the honours fairly equally. The chapters on symptomatology are clear and tersely written. Physical examination is described in detail, with particular attention to the importance of percussion, and the account of auscultatory signs is admirable in its simplicity and avoidance of the confusion arising from the use of practically synonymous terms, a snare to which so many writers on pulmonary tuberculosis succumb. Radioscopic examination is allowed a prominent place in diagnosis. Nearly half the volume is devoted to treatment, especial attention being paid to the therapeutic use of tuberculin. The indications for and technique of the operation for artificial pneumothorax are excellently discussed, but on the whole the book is rather disappointing. It is mainly a painstaking compilation of other authors' views, and we miss the personal experience and deliberate judgement which Professor Klemperer may be credited with possessing and which would have lent interest to his book.

Dr. WALTERS's book on the *Domiciliary Treatment of Tuberculosis*⁵ is designed to furnish the practitioner with a compact and reliable guide to the treatment of pulmonary tuberculosis. The first hundred pages deal with diagnosis, home conditions, general methods of treatment, and the relation of health and infection to ventilation and cleanliness. The remainder of the book is given to the methods of treatment, special and general, found best in the various contingencies of the phthisical patient's life. Dr. Walters writes clearly, and perusal of his pages makes it obvious that he has had great experience in dealing with consumptive patients. He gives full accounts of the numerous specific and general remedies for tuberculosis that have had or perhaps are still having their day; it is possible that the general practitioner would be glad to have the author's opinion as to their real value more often than it is given. The book may be recommended as an up-to-date and thoroughly practical account of the subject with which it deals.

PATHOLOGY OF THE NERVOUS SYSTEM.

IN a brief preface to their volume entitled *Pathology of the Nervous System*⁶ the authors, Drs. BUZZARD and GREENFIELD, state their belief that in offering it to medical students and practitioners they are meeting a real need. We may say at once that they may be congratulated on having admirably achieved their object. Such a monograph is a valuable addition to the information available in the ordinary textbooks of medicine. No attempt has been made to enter deeply into disputed questions of histology or pathogenesis, but the ordinary morbid anatomy, both naked-eye and microscopic, of the diseases of the nervous system is well described throughout and interest is stimulated by a brief consideration of the relations between the anatomical and the clinical phenomena. The first three chapters contain a succinct but comprehensive account of the doctrine of the nature of the neurone and of its degeneration and regeneration. This is supplemented in the next two chapters by accounts of the paths of infection in the central nervous system and by an excellent description of the cerebro-spinal fluid and the changes which it exhibits in various diseases. In the next section, dealing with the developmental and familial diseases, short but adequate descriptions of the morbid anatomy are given and enough clinical details to render the account more valuable. Chapters on injuries and circulatory disturbances of the brain and spinal cord follow. The chapter on syphilis of the nervous system is good and concise; the chief forms which it may assume are described separately, while insistence on the essentially identical processes at work is emphasized in a preliminary account of the general features of the syphilitic lesion.

In the section on other infective diseases there are particularly useful accounts of poliomyelitis and lethargic encephalitis. Special praise must be accorded to the chapter on tumours of the brain and spinal cord, which is richly illustrated by many admirable plates. Among the diseases of obscure origin we find satisfactory accounts of the pathology of disseminated sclerosis and subacute combined degeneration of the spinal cord. Two useful appendices contain brief

Maloine et Fils. (Tome xvii: Demy 8vo, pp. 387; 16 figures, 2 plates; Fr.20. Tome xviii: Demy 8vo, pp. 811; 48 figures, 9 plates; Fr. 35.)

⁴ *Die Lungentuberkulose; ihre Pathogenese, Diagnostik und Behandlung*. By Professor Dr. Felix Klemperer. Berlin and Vienna: Urban and Schwarzenberg. (Sup. roy. 8vo, pp. 164; 5 plates, 16 figures. M.40.)

⁵ *Domiciliary Treatment of Tuberculosis*. By F. Rufenacht Walters. M.D., B.Sc., M.R.C.P.Lond., F.R.C.S.Eng. London: Baillière, Tindall and Cox. 1921. (Demy 8vo, pp. 302; 3 figures. 12s. 6d. net.)

⁶ *Pathology of the Nervous System*. By E. Farquhar Buzzard, M.A., M.D., F.R.C.P., and J. Godwin Greenfield, B.Sc., M.D., M.R.C.P. London: Constable and Co., Ltd. 1921. (Med. 8vo, pp. xv + 334; 102 figures. 30s.)

descriptions of staining methods and details of the examination of the cerebro-spinal fluid.

The numerous photographs, both macroscopic and microscopic, with which the book is lavishly supplied, are a feature of great value; another useful feature is a short bibliography at the end of each chapter. The book has been brought well up to date, as the accounts of lethargic encephalitis and of such subjects as Lange's colloidal gold test will show. It is in no sense a work of reference for the professed neurologist, but rather a manual for those who desire more detailed information on pathology than can be supplied by the usual textbooks of medicine or neurology.

Unfortunately, the costs of printing and illustrating have combined to enhance the price of this volume, so that it may, we fear, prove somewhat high for students without much money to spare for books outside those which are absolutely necessary. To the more senior student, and especially those who intend to devote particular study to neurology, this volume will come as a thoroughly reliable and almost essential addition to their library.

UROLOGY.

THERE is no specialty in medicine that combines so fully the interest of surgeons and physicians as urology. For this reason a work like Marion's *Traité d'Urologie*⁷ should appeal to a very great number of readers. Written as it is with an admirable lucidity, and illustrated with excellent plates, it should be of interest not only to those who have become experts in this particular domain of medicine, but to all practitioners. One of the chief assets in the science of urology is the exactness of its methods of diagnosis, and the author has done well to devote considerable space to the description of methods of exploration. He has even included a brief survey of the commoner laboratory investigations required in the complete examination of a case. This summary should prove useful to those surgeons who carry out the simpler laboratory examinations in their own consulting rooms. The third portion of the work is devoted to signs and symptoms. The value and significance of pain as an indication of disease in the genito-urinary tract is fully dealt with. The section on haematuria as a diagnostic sign is particularly good. Following this comes the section on pathology, using the term in its most comprehensive sense to embrace the study of the causation, pathological anatomy, symptoms, diagnosis, and prognosis of disease. A useful addendum to the chapters devoted to treatment is a list of formulae and specimen diets used in the treatment of various pathological conditions. Authors not infrequently diminish the value of their recommendations as to treatment by failing to supply their readers with those details which may make all the difference between success and failure. By giving the exact formulae of various therapeutic agents and actual diets suited to different diseases Marion has avoided this error. The chapters on operative technique are well illustrated, so that the majority of the operations described may be understood with a minimum of labour. The work concludes with a series of coloured plates of urethroscopic and cystoscopic views. The quality of these varies considerably; some of them are realistic, whereas others err on the side of overcolouring. Some of these plates have already appeared in previous publications by the same author. The treatise is, for the convenience of the reader, published in two volumes. Considering the excellence of the printing, the workmanship of the plates, and the quality of the paper, the price charged for the work cannot be considered excessive. Altogether both the author and the publishers are to be congratulated on the result.

To the second edition of his *Traité Chirurgicale d'Urologie*⁸ M. Félix Legueu has made many notable additions, especially in the matter of illustrations and coloured plates. Urology has made considerable progress since the appearance of the first edition in 1910, and as a result many of the chapters have been considerably modified and augmented. The author's appointment to the professorial chair formerly held by Guyon has given him facilities for drawing on the clinical material of the Necker Hospital, and much of the new matter included in the present work has been derived from the laboratory,

out patients' department, and the museum of that institution. The chapter on tests of renal function has been to a great extent rewritten, since it is only during the last ten years that the importance of this subject has been recognized. In summing up the value of the various tests that may be applied the author points out that we have no absolute criterion of the health of a kidney. We can only speak in relative terms, hence the necessity of multiplying the controls and tests; in the multiplicity lies safety, and only by the conscientious use of all the means of exploration at our disposal can we avoid the pitfalls which surround the practice of renal surgery. A new feature of the work is the chapter on the pathology of the suprarenal capsule, although, as a rule, these structures receive scant attention from genito-urinary surgeons. The association between the suprarenal capsules and the kidneys is, however, so intimate that it is probably wise to include the description of them and their lesions in a work that aims at being as complete as that under review. Another new chapter is that which deals with pararenal growths and perirenal haematomata. The experiences of the late war have added much to our knowledge of gunshot wounds of the kidneys and urinary tract. This has necessitated an expansion of the chapter devoted to this subject as well as the development of the paragraph dealing with plastic methods of repair. Other features of the new edition are the use of local anaesthesia in prostatectomy, a description of the vesico-transperitoneal route for the closure of a vesico-vaginal fistula, and the study of the preter after nephrectomy. Many new illustrations and plates have also been added. As a result of this great increase in illustrations and text alike it has been necessary to divide the work into two volumes. However high may have been the reputation of the first edition, we have little doubt that the second will have a greater, for it is one of the completest works on urology that has yet been published. Dr. Félix Legueu, with the great facilities of the Necker clinic at his disposal, is well qualified to edit such a work, and his present volumes reflect credit, not only on the clinic of the Necker Hospital, which he administers, but also on the French school of genito-urinary surgery in general.

A HANDBOOK FOR THE MAIMED.

ALTHOUGH a man who has some teeth left is not called toothless, and one who has two or three coppers cannot strictly be called penniless—and many other analogies might be cited—yet it appears that one may have three-fourths of the normal allowance of limbs and yet be described as "limbless." It would show more sense of the meaning of words, and so be more logical, if less euphonious, to follow the French example and use the term "amputee," on the analogy of payee, employee, and trustee. The authors of the *Handbook for the Limbless*⁹ are, however, not the original sinners in this respect, and, whoever may have been the first offender, the misnomer has been adopted by the Ministry of Pensions, thus showing how poor a safeguard against the commission of blunders in the use of English is the competitive examination of the Civil Service Commission.

Apart from its title, we have nothing but praise for this small book, from the foreword (there is a preface too) by Mr. John Galsworthy to the excellent index. It has been published, and is sold at less than cost price, with the good intention of giving the maimed man all the information which is likely to be useful to him in connexion with his disablement. The report of the committee of inquiry into the comparative advantages of metal and wooden limbs, which was noticed in our issue of November 12th, 1921, p. 805, occupies the first place in the book. The interesting account of the disabled drivers' rally, held last June in Richmond Park, after tests on Epsom Downs, shows how well arm and leg amputees can manage motor cars, even without any special fittings, but certain special attachments which have been found useful are shown in the illustrations. This demonstration and the records of amputee drivers prove that there is no reason to consider them more liable to accident than unimpaired men. The handbook contains many useful hints the outcome of the experiences of the wearers of artificial limbs, and full instructions in exercises and muscle training for those who have lost a leg are given by Miss M. Randall and Mr. G. A. Ponsonby. Detailed information is also given as to

⁷ *Traité d'Urologie*. Vols. I and II. Par G. Marion. Paris: Masson et Cie, 1921. (Roy. 8vo., vol. I, pp. xx+1 to 572; 160 figs.; vol. II, pp. 573 to 1052; 15 plates, 258 figs. Fr. 120 net.)

⁸ *Traité Chirurgicale d'Urologie*. Vols. I and II. Par F. Legueu. Dernière édition, revue et augmentée. Paris: F. Alcan, 1921. (Sup. roy. 8vo., vol. I, pp. 1 to 934; 335 figures, 6 plates; vol. II, pp. 935 to 1351; 523 figures, 5 plates. Fr. 160 the two vols.)

⁹ *Handbook for the Limbless*. Edited by G. Howson. Published by The Disabled Society, 43, Grosvenor Square, London, W.1. (Demy 8vo., pp. xiii+225, with illustrations in the text. Price 1s., or 1s. 4d. post free.)

the opportunities for training and employment offered to the disabled. An interesting section upon sports, including swimming, riding, and boxing, is contributed by General Sir E. C. Botham, Captain du Buisson, Major P. A. Leahy, and others. Full particulars are given of the pensions and allowances to which amputees are entitled.

After looking through this book the reader is more than ever impressed by the pluck and spirit of the disabled, and is confirmed in the opinion that what matters most is the determination to succeed despite all difficulties.

SYNTHETIC DRUGS.

THE number of synthetic drugs is enormous, and the aim of Dr. PERCY MAY, in his book on *The Chemistry of Synthetic Drugs*,¹⁰ has been to give a clear account of the principles which underlie their production. In spite of the fact that the relation between chemical structure and physiological action is by no means rigid, it serves as an indication of the roads along which investigations should be pursued. The opening chapters, devoted to the study of the theory of action of synthetic drugs, the effect of the introduction of various elements and radicles, and the chemical changes which drugs undergo in the organism, are of interest. Other chapters deal with local and general anaesthetics, antipyretics, antiseptics, purgatives, and the organic preparations of arsenic and antimony.

The methods of preparation of the more important substances are indicated, and throughout numerous references to the literature and to patent specifications are given. It will be observed that for the most part the references are to German literature; and it must be admitted that prior to the war the industry was almost entirely in German hands. Since that time much has been done in this country, and it is to be hoped that the enterprise of our manufacturers will provide our chemists with the necessary facilities and stimulus to prosecute research for new compounds which may have value in practical therapeutics. Perusal of this book cannot fail to stimulate; it is well up to date, and will be of great value to all interested in the subject of synthetic drugs.

NOTES ON BOOKS.

THE thirty-eighth annual volume of *The Year Book of the Scientific and Learned Societies of Great Britain and Ireland*¹¹ contains much information that would not otherwise be available without much trouble and research. To prepare a classified outline of the higher intellectual work in this country during the past twelve months, as it has found expression through the numerous learned and scientific societies, cannot have been an easy task, and much credit is due to the publishers, who from year to year continue to make this useful contribution to the advancement of science. The different sections of the volume include science generally; astronomy, mathematics, and physics; geography, geology, and mineralogy; biology, including microscopy and anthropology; economic science and statistics; mechanical science and architecture; law; literature, history, and music; archaeology; and, among others, medicine. In the section devoted to medicine are found details of the personnel of the Ministry of Health, the names of the principal officers, and the titles of the papers read at the Annual Meeting of the British Medical Association, the titles of the papers read at all the sections of the Royal Society of Medicine, the titles of the publications issued by the Medical Research Council during the year, and of the scientific papers published from the Lister Institute, together with similar details of the leading medical societies in London and throughout the provinces, Scotland, and Ireland.

*Willing's Press Guide*¹² is a useful compilation, giving particulars of the address and price of periodical publications issued in Great Britain and Ireland, and information also with regard to colonial and foreign newspapers, with the addresses of their London offices. It contains two pages of antiquarian interest, in which a list is given, with notes, of existing newspapers and periodicals founded in the seventeenth and eighteenth centuries; in many instances there has been a change of title, but continuity has been maintained. Leaving aside the *London Gazette* (first called the

Oxford Gazette, publication having been begun there in 1665), the *Edinburgh Gazette*, and the *Dublin Gazette*, the oldest newspaper is believed to be the *Worcester Post*, founded in 1709. Within the next quarter of a century newspapers were founded in Nottingham, Stamford, Bristol, Hereford, Norwich, Canterbury, Leeds, Northampton, Gloucester, Reading, York, Salisbury, Chester, and Derby. The first newspaper in Ireland seems to have been the *Belfast News* (1737), and the first in Scotland the *Aberdeen Daily Journal* (1748).

Dr. CHAVASSE'S *Advice to a Wife*¹³ has been such a worthy classic for a generation that the appearance of a new edition calls for brief notice only. This is the seventeenth authorized edition, and altogether four hundred and fifty thousand copies of the various editions have, it is stated, been issued. No wonder that Dr. G. T. WRENCH felt, when called upon to revise the book for this new edition, that to alter it beyond what was absolutely required by the march of progress would savour of sacrilege. As he well puts it: "Chavasse shows such a perfect handling of his theme, he is so wise, so genial, so trustworthy, so pillared with the best of English literature, that to change his book seemed to me as unfortunate a necessity as it is to renovate a beautiful yet timeworn building." That is the right spirit to show towards such a book, and it will suffice to say here that Dr. Wrench has succeeded in his process of "restoration" so completely that not even the connoisseur can raise a protest. There is no book of its kind that we can more cordially recommend to the young married woman who wishes a guide to the management of her own health.

The sixth annual report of the National Council for Combating Venereal Diseases, covering the period from June, 1920, to June, 1921, has just been issued.¹⁴ It contains lists of officers, committees, and members of the Council; a report of the annual meeting and the address of the President, Lord Gorell; and a general account of the Council's activities during the period under review, together with the balance sheet and statement of accounts. Fifty pages are devoted to overseas branch reports and home branch reports. The branches of the Council now number 81 in England, 4 in Scotland, 7 in Wales, 1 in Ireland, and 10 overseas.

¹⁰ *Chavasse's Advice to a Wife on the Management of Her Own Health*. Revised by G. T. Wrench, M.D., B.S.Lond., Seventeenth edition. London: J. and A. Churchill. (Cr. 8vo, pp. 345. 2s. 6d. net.)

MEDICINAL AND DIETETIC PREPARATIONS.

Vaccines by the Mouth.

ANTIDYSENTERIC tablets and antityphoid and bile tablets are, the proprietors state, vaccines prepared according to the instructions of Professor Besredka, and are intended for oral administration. Besredka has advocated the administration of antityphoid and antidyenteric vaccines by the mouth. He found that typhoid vaccine when so given was efficacious only when bile was added, but that bile was not necessary in the case of the antidyenteric vaccine. Besredka claims that "the method of vaccination per os realizes three essential conditions: it is harmless, it is efficacious, it is rapid" (*Bull. de l'Institut Pasteur*, vol. 18 February 29th, 1920). It is obvious that if vaccines can be prepared which are efficacious when given by the mouth a very great therapeutic advance has been made. Anyone who served as medical officer to a battalion during the war will appreciate how much labour and trouble such an antityphoid vaccine would have saved a few years ago. Besredka's views as to the efficacy of vaccines given by the mouth have not, however, met with general acceptance, and the value of these preparations is still, therefore, a matter of uncertainty. The agents in this country are the Sealand Trading Company, Buchanan Buildings, 24, Holborn, London, E.C.1.

Coagulen-Ciba.

Coagulen-ciba is an extract obtained from blood platelets, and is recommended as a haemostatic suitable for oral, hypodermic, and intravenous administration. We find that the substance, when injected intravenously, causes a distinct shortening of the coagulation time of rabbit's blood, and does not produce any marked toxic effects. One gram of coagulen-ciba represents 20 grams of dried blood, and it contains a large amount of thrombokinase. The preparation is recommended for local application as a haemostatic, and also for hypodermic or intravenous use in cases where the coagulation of the blood is deficient. Good clinical results are reported by numerous authors. Coagulen-ciba is supplied in powder,

British Medical Association.

CURRENT NOTES.

The Medical Officer of Health for Manchester.

THE Manchester City Council is advertising for a medical officer of health in succession to Dr. Niven, whose term of office is nearly over. It is offering a salary of £1,500 a year, without any bonus and without any promise of increments, and the British Medical Association declines to insert the advertisement, in which action it has the cordial support of the Society of Medical Officers of Health and of the *Lancet*. It is hardly to be supposed that any candidate who would be considered suitable for what is one of the outstanding public health posts in the kingdom will apply for it in the face of the strong objections held by the medical bodies chiefly concerned. We are informed that the town clerk on appointment receives £2,250, with the prospect of an early rise to £3,000; the engineer receives £3,000, with outside fees; but (as our informant caustically remarks) these officers are dealing with money, while the medical officer of health is only dealing with health. It is essential that all sections of the medical profession should realize that the offer of such a salary for such a post is a reflection not only on the public health section of the medical profession, but on the whole profession, and is, moreover, a menace. The office of medical officer to a city like Manchester may be regarded as one of the prizes of the profession on the public health side. The salary, if accepted, would certainly be used as a precedent by other large cities and by other employers of medical practitioners. If £1,500 is to be regarded as a suitable salary for such an officer the effect on the salaries and remuneration of other medical men and women in other responsible posts can easily be estimated. It is hoped that any medical man who has already applied for the post will withdraw his application at once.

Annual Meeting, Glasgow, 1922.

In a printed letter, inviting members of the Lanarkshire Division to be present at the Divisional meeting this month, the Chairman, Dr. John Lithgow, gives a sketch of the plan and purpose of the Annual Meeting of the British Medical Association to be held in Glasgow next July. In the belief that the information Dr. Lithgow gives will be of interest to members outside his Division, we quote the following extracts:

It is thirty-four years since the Association last met in Glasgow, and it is expected that more than 2,000 members of our profession will be present from all parts of the world. The meeting will be presided over by Sir William MacEwen, F.R.S., C.B., LL.D. Arrangements are being made by the Glasgow and West of Scotland Branch for the scientific meetings, the Representative Meeting, and the meetings of various sections in surgery, medicine, etc. An interesting programme of entertainments and excursions to

places of interest is also being drawn up, and it is hoped that the Glasgow meeting will be one of the most successful in the history of the Association.

The Lanarkshire Division is the largest in the West of Scotland Branch, and the third largest in Scotland. The membership, which was 66 in 1904, has now more than doubled, but in the whole county of Lanark there are still more than 150 members of the medical profession who are not members of the British Medical Association. I feel that this is a specially appropriate occasion for increasing the membership, as the meeting is to be held in Glasgow, when we will be meeting our brethren from all over the kingdom, the Overseas Dominions, and from abroad. We must unite to give them a hearty Scottish welcome; many of those who served overseas during the war will have an opportunity of meeting old comrades and extending hospitality to them.

Professional Organization.

The *National Veterinary Journal*, whose editor is Professor Frederick Hobday, C.M.G., publishes this month an editorial article headed "Waken Up!" in which a moral is drawn for the veterinary profession from the growing success and strength of the British Medical Association. Our contemporary, taking as its text a Current Note printed in a recent issue of the SUPPLEMENT, writes as follows:

"At a recent meeting of the Propaganda Subcommittee of the British Medical Association the report of the Financial Secretary showed that no less than 856 new members had joined the Association between June 21st and October 6th, 1921; 123 members paid arrears of subscription, and 15 resignations were withdrawn. Resignations numbered 88, and there were 70 deaths. The sum total gave a total membership on October 6th, 1921, of 23,634, as compared with 22,793 on June 20th. As stated in the *British Medical Journal*, the official organ of the Association, 'such figures speak for themselves.' It is a worthy example of what can be done in a 'five' profession, and the figures are worthy of comparison as to whether we are in as good a case. True, the medical profession is numerically very much in excess of ours, but proportionately the number of active members is greater, and it ought not to be so.

"Our National Veterinary Association and its official journal proportionately, as is the British Veterinary Association, be, too, when once the profession is entirely our own fault in this, as in other matters, that it is not so, and we have only to refer to the correspondence columns of this issue to see even laymen are not oblivious of the fact; and very often the members of our profession who do the least for their fellow-men make the most complaint. The remedy lies with ourselves, and if we will but act up to our motto, 'Vis Unita Fortior,' and each 'waken up' and put his shoulder to the wheel, we cannot possibly fail to command, every one of us, an income and a social position worthy of a learned profession. . . . Let us then start the year each promising to do something for himself and his profession; not forgetting that in our union lies our strength, and that by each federating himself with the parent body and by spreading the knowledge his experience has acquired to his fellow practitioners he is benefiting not only the world in general but himself in particular."

It is gratifying that our Association and its journal should be held up as an example of professional organization. But the good work of 1921 must be pressed forward and consolidated in 1922. Progress stops when complacency sets in.

Statistics as to Insurance Work.

At the outset of the discussions between the Insurance Acts Committee and the Ministry of Health regarding the 1920 capitation fee, the former found of considerable value the statistics of work done which insurance practitioners had supplied to the Medical Secretary.

The need for this information will be equally great when the present capitation fee is reviewed at the end of 1924. Insurance practitioners are therefore requested to forward to the Medical Secretary information under the following heads with respect to 1921:

Name.	Insurance Address.	No. of Insured Persons on List.	No. of Insured Persons Attended during 1921—that is, No. of Patients.	No. of Consultations.	No. of Visits.

Meetings of Branches and Divisions.

NORTH OF ENGLAND BRANCH.

A MEETING of the combined Cleveland and Stockton Divisions was held in the North Riding Infirmary, Middlesbrough, on January 12th. The attendance was slightly disappointing, due doubtless to the prevalent influenza. Mr. W. S. DICKIE, chairman of the Cleveland Division, presided, and the meeting was addressed by Dr. ALFRED COX, Medical Secretary, who took for the title of his address "Is the British Medical Association of any use to the medical profession?" Dr. Cox divided his speech into three sections: (a) National Health Insurance; (b) the preventive and curative aspects of the public health; (c) the relation of the profession to the hospitals. He dealt with these subjects in able fashion, and was listened to with great interest. The subsequent discussion was taken part in by Drs. BROWNLEE, HENRY, LEVICK, LOWE, JACKSON, LYLE, and HOWELL. Dr. Cox replied to questions and criticism, which at times threatened to become rather warm, and was accorded a hearty vote of thanks for his kindness in coming to address the meeting.

Association Notices.

MEETING OF COUNCIL.

The next meeting of Council will be held on Wednesday, February 15th, in the Council Room, 429, Strand, London, W.C.2, at 10 a.m.

BRANCH AND DIVISION MEETINGS TO BE HELD.

DORSET AND WEST HANTS BRANCH: WEST DORSET DIVISION.—A meeting of the West Dorset Division will be held at Dorchester, on Wednesday, February 8th, when Dr. J. S. Fairbairn (London) will give a British Medical Association lecture, entitled "What disability is caused by and what treatment is required for internal displacement?"

EAST YORKS AND NORTH LINCOLN BRANCH: EAST YORKS DIVISION.—A meeting of the East Yorks Division will be held at Hull, on Friday, February 10th, when Sir Frederick Mott, F.R.S., will deliver a British Medical Association lecture on "The reproductive organs in relation to mental disorders."

METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.—A meeting of the Lewisham Division will be held on Tuesday, January 24th, at 8.45 p.m., at Farnboro' House, Kirkdale, Sydenham, S.E.26, when Dr. G. W. Charsley will occupy the chair. Dr. B. A. Richmond will give an address on "Developments of the medical service."

SOUTH MIDLAND BRANCH: BEDFORD DIVISION.—A general meeting of the Bedford Division will be held on Tuesday, January 31st, at the Bedford County Hospital, at 3 p.m. Agenda: Consider Annual Report of Council; discuss the proposed reduction of the Dispensing Capitation Fee; elect Representative and Deputy Representative; consider appeal for the Wood-Hill Fund. Dr. Glendinning will read a paper on "The diagnosis and treatment of gastric ulcer."

SUSSEX BRANCH: BRIGHTON DIVISION.—The series of clinical demonstrations arranged by the Brighton Division will be continued at 4 p.m. on Thursdays on the dates and at the hospitals indicated. Tea will be provided at 3.45 p.m. The demonstrations are open to all members of the profession, but those not already members of the Association are invited to make application for membership, the advantages of which are very great. February 16th, County Hospital (cases from special departments); March 16th, Ldy Chichester Hospital, New Church Road, Hove; April 20th, County Hospital (medical cases); May 18th, Children's Hospital; June 15th, County Hospital (surgical cases).

WILLESDEN HEALTH POLICY.

The following correspondence has taken place between the British Medical Association and the Ministry of Health in regard to the medical service instituted by the Willesden Urban District Council. The circular mentioned by Dr. Cox is the leaflet reproduced in full in the SUPPLEMENT of December 24th, 1921, p. 255, and discussed in a leading article in the JOURNAL of November 26th, 1921, p. 908:

19th December, 1921.

Sir,

The Council of the Association, at its meeting on the 14th inst., gave protracted attention to the situation which has recently arisen at Willesden in connexion with the activities of the Willesden Urban District Council. I am directed to send to you a copy of a circular issued by that council and to ask the Ministry to at once take action with regard thereto. In the opinion of the Council the policy outlined in this circular is contrary to the policy laid down by this Association as representing the general body of the profession, against the interests of the public, and would also appear to be directly contrary to the declared policy of the Ministry of Health.

I shall be glad to hear in due course what action the Minister proposes to take.

I am, Sir, your obedient servant,

(Signed) ALFRED COX,

The Secretary.

Ministry of Health, Whitehall, S.W.1.

Medical Secretary.

Ministry of Health, Whitehall, S.W.1,
12th January, 1922.

Sir,

I am directed by the Minister of Health to advert to your letter of the 19th ultimo and enclosure relating to the scale of charges for medical services recently introduced by the Willesden Urban District Council, and to state that the Minister has informed the Council that he is not prepared to agree to the proposed annual registration fee of 2s. 6d., and he has requested the Council to rescind this part of the scheme.

The Minister's view is that no charge should be made for preventive as distinguished from remedial services in connexion with maternity and child welfare—that is, for such services as the visiting of homes by health visitors, attendance of mothers and of children under five at consultation centres, and educational facilities provided at maternity and child welfare centres for expectant and nursing mothers. It is desirable that any mothers and children, and especially the more necessitous, should have the opportunity of profiting by these important services if they so desire.

When, in the administration of the preventive services referred to, mothers and children are found to need further medical advice and treatment, the Minister considers that they should be advised to obtain it from private medical practitioners, and that treatment should be provided by the local authority only for cases in which the parent is unable for sufficient reason to obtain it from a medical practitioner or for ailments which experience shows are not generally treated unless provision is made by the local authority.

I am, Sir, your obedient servant,

(Sgd.) W. A. ROBINSON.

A MEETING of the Willesden Division of the British Medical Association was held on January 17th, when the Willesden Urban District Council's letter of December 21st, 1921 (see SUPPLEMENT, January 7th, 1922, p. 5) received consideration. An animated discussion took place, and a detailed reply to the letter was drawn up. The reply opened by expressing regret that the Willesden Council had not only failed to deal with the general argument set forth in the Division's original memorandum on the subject of the Willesden Public Health Services, but had so far failed to appreciate the Division's meaning in several respects as to reply to several propositions which had not been advanced.

The letter from the Urban District Council was criticized at some length in the BRITISH MEDICAL JOURNAL of January 7th (SUPPLEMENT, p. 4), and the letter from the Willesden Division covers practically the same ground. The Division points out that it was in recognition of the council's position as public health authority for the district, and in the belief that the welfare of the community and the policy of the

Ministry of Health aliko demanded the active co-operation of all agencies in the promotion of public health, that it approached the council in the first instance with a criticism of the existing health policy. The letter by the Division proceeds:

In reply to paragraphs 5, 6, and 18, the Division welcomes the suggestion that it should submit a scheme for working in the council's hospitals and clinics, but would point out that an indispensable preliminary to such co-operation is the creation of an advisory medical council on the lines indicated in the Dawson Report, and that the essential condition of such co-operation will be modification of the existing system in accordance with the principles already laid down. It will be clear to the council that the Division cannot co-operate in the maintenance of a system created without consultation with the local profession and in opposition to the declared policy of the British Medical Association and to the guiding principles laid down by the Ministry of Health and successfully followed elsewhere in the country.

As regards the question of public health, the Division does not desire to enter into correspondence on points of administrative detail within the province of the council's responsible officials. The points at which, in its opinion, the council's present policy is not conducive to the public welfare have already been sufficiently indicated. Should the council desire to raise any specific question as to the matters set forth in the original memorandum the Division will be glad to reply.

Among the suggestions put forward by the Division as possible economies in public health administration, which the council had asked for, is the adoption of the Darncliffe scheme, by which a large amount of treatment of school children could be carried out by the local practitioners at their surgeries or in the children's homes. A simplification of the system of records is also recommended, and it is pointed out that conditions in Willesden hardly justified the expenditure of £6 per birth in regard to maternity work, as against £2 per birth in other comparable districts. The Division, quoting from the report of the Chief Medical Officer of the Board of Education, shows that the Willesden health policy is in direct opposition in many important respects to that outlined in the publications of the Ministry of Health and of the Board of Education. The infant mortality figures, which have already been given in these columns (SUPPLEMENT, January 7th, 1922, p. 4), are emphasized, and the danger of founding statistical arguments upon isolated figures is again pointed out. As regards the municipal hospital and clinics the Division states:

In paragraphs 8 to 14 the council makes certain statements with regard to the utilization of the Municipal Hospital. The Division welcomes the statement that the proposal to limit admission to the hospital to certain districts of Willesden contained in the twenty-fifth annual report has not been carried out, and is glad to learn that the utilization of one block of the hospital for maternity cases has not so far led to any fatalities. It is not, however, satisfied that the hospital is being used to the best advantage, or that there is sufficient justification for the exclusion of urgent infectious cases in order to accommodate non-infectious cases and normal maternity cases. For such cases the London hospitals, the Willesden General (Voluntary) Hospital, and the Park Royal Hospital are available, and could be utilized by private practitioners when necessary.

Turning to paragraph 15, the Division is astonished to learn of the position in respect of the council's clinics. It would be glad to know what class of patient has ceased to attend the clinics. If the more accessions mothers are actually unable to afford the registration fee of 2s. 6d. their exclusion from the benefits of the clinic appears particularly unfortunate. If, on the other hand, the more well-to-do mothers do not consider the treatment obtained at the clinic worth the amount charged, such a result hardly appears to support the council's contention.

Finally (the reply concludes), the Division would like to make it clear that it has not entered into the controversy merely for the sake of controversy, and that its members claim to be as much concerned about the health of the Willesden community as the council is. As doctors they believe they have the knowledge and experience which justifies them in criticizing the methods of the Health Committee. As ratepayers they think they are justified in taking exception to expenditure which, in their opinion, could be avoided without injury to the community—in fact with benefit to it. The Division believes that the duty of the Willesden Urban District Council to safeguard the health of the community would be better carried out if it confined itself to strict and earnest attention to preventive medicine. It has a staff specially trained for that purpose, and the general practitioners in the area are quite willing and able to look after the curative side, both as private practitioners for people who can pay for themselves, or in co-operation with the council for people unable to provide medical treatment without help. The council and the Willesden public doctors in an effort to improve the establishment of a medical advisory council elected by the medical profession of Willesden. It would be the duty of that body to place its opinions on medical matters before the elected representatives of the community. The final responsibility would be with the council.

Insurance.

NATIONAL INSURANCE FINANCE.

THE British Medical Association has been asked by a Local Medical and Panel Committee to arrange for publication in the JOURNAL of a synopsis of Appendix X, published on pages 208 and 209 of the Second Annual Report for 1920-21 of the Ministry of Health. This gives an abstract of cash receipts and payments into the National Health Insurance Fund (England) for the year 1920.

Under the heading of receipts, which amount in total to £26,959,165, the following are the principal items: Balance at December 31st, 1919, £361,110; from sale of Insurance Stamps, £18,831,311; contributions on behalf of seamen, marines, soldiers and airmen, £109,717; Exchequer grants, £6,957,592; Ministry of Pensions towards cost of benefit of invalided seamen, marines, soldiers and airmen, £175,000; interest of investments in securities selected by societies held by Commissioners on behalf of societies, £35,376.

The payments fall short of the receipts by the sum of £936,188. The principal items of expenditure were: Societies for benefits and expenses of administration, £10,264,344; Insurance Committees for medical and sanatorium benefits and expenses of administration, £10,116,617; war bonus allowances to medical practitioners, £52,849; deposit contributors for benefits, etc., £55,284; Navy and Army Insurance Fund, £109,656; payment to married women under Section 22(8) of National Insurance Act, 1918, £20,290; refund of maternity benefits paid by other Government departments, £9,907; refunds on account of insurance stamps returned to Ministry of Health, £7,064; Exchequer for expenses of administration of Deposit Contributors Fund, Navy and Army Insurance Fund, Exempt Persons Fund, and Approved Societies (Officers) Guarantee Fund (England), £54,569; Ministry of Labour contributions under out-of-work donation scheme (refund), £113,000; contributions to Approved Societies (Officers) Guarantee Fund, £6,783; payments to Special Fund constituted under Section 27 of National Insurance Act, 1918, £125,500; miscellaneous payments issued to societies for investment, £3,048,365; purchase of investments on behalf of societies, £1,068,979; National Debt Commissioners for temporary investment, £850,000; transfers to National Insurance Funds, other countries, £97,354.

CERTIFICATE BOOKS.

INSURANCE medical practitioners are asked to note that the price of the National Health Insurance Acts Certificate Books, supplied for their use by the British Medical Association, is now 9d. each, and not 6d. as formerly. Applications for the Certificate Books should be addressed to the Financial Secretary, 429, Strand, London, W.C.2.

Correspondence.

The Mileage Grant.

SIR,—I have received a number of letters from rural practitioners asking me if I consider the reduction of the mileage grant is in accordance with the Minister's statement on October 11th last, "that the arrangements in force now regarding mileage and things of that kind should remain in force as in the past." May I answer briefly through your columns?

The "arrangements now in force" included a committee then sitting to consider the new statistics and advise upon the assessment for 1921. This committee has now reported, and Mr. Harris's letter to Insurance Committees alludes to its findings. They involve a reduction of the main portion of the fund (ordinary mileage) by some 15 per cent. as compared to 1920, and this, I think, practitioners must accept as no breach of a common-sense interpretation of the Minister's promise.

But the reduction of the special portion for districts of extraordinary difficulty is contrary to the recommendation of the committee, and I cannot myself see how it can be reconciled with the Minister's words.

The whole subject will, however, be considered at the next meeting of the Insurance Acts Committee.—I am, etc.,

Weyhill, January 15th

J. P. WILLIAMS-FREEMAN.

At a meeting of the Dundee Panel Committee on December 28th, Dr. C. S. Young, who lately retired from the chairmanship of the Committee, was made the recipient of a handsome silver tea and coffee service, subscribed by present and former members of the Dundee Panel. Dr. G. W. Miller, D.S.O., the present chairman, in handing over the gift, referred to the valuable services rendered to the profession by Dr. Young as chairman of the Committee from its inception until now. Mention was also made of the kindness of Mrs. Young as hostess to the Committee at their frequent meetings. Dr. Young replied appropriately on behalf of Mrs. Young and himself.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following notifications are announced by the Admiralty:—Surgeon Commander A. W. B. Livesey has been placed on the retired list, with the rank of Surgeon Captain; Surgeon Commander L. F. Cope, O.B.E., to the *Marlborough*, on commissioning; Surgeon Lieutenant L. F. Wallace to the *Victory*, additional, for R.N. Hospital.

ARMY MEDICAL SERVICE.

ROYAL ARMY MEDICAL CORPS.

Major and Brevet Lieut.-Colonel C. W. Holden, C.M.G., D.S.O., to be temporary Lieutenant-Colonel whilst employed as Assistant Director of Hygiene.

Temporary Captains relinquish their commissions and retain the rank of Captain: R. J. Harris, H. Cardin, I. Ridge-Jones, M.C.

ROYAL AIR FORCE MEDICAL SERVICE.

G. Kinnear is granted a short service commission as a Flying Officer, with effect from, and with seniority of, Dec. 10th, 1921.

Flight Lieutenant R. W. Ryan is granted a short service commission, retaining his present substantive rank and seniority.

SPECIAL RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

Captain C. S. Sandeman, to be Major.
Captain D. Mackie, M.C., relinquishes his commission, and is granted the rank of Major.

TERRITORIAL ARMY.

ROYAL ARMY MEDICAL CORPS.

The following officers, having attained the age limit, are retired, and retain their rank except where otherwise stated: Lieut.-Colonels W. Blair, T.D., and J. L. London, T.D., with permission to wear the prescribed uniform; Major T. Frankish, T.D., and is granted the rank of lieutenant-colonel with permission to wear the prescribed uniform; Majors S. W. Plummer, T.D., D. G. Newton, T.D., D. G. Campbell, T.D., Brodie, M.B.E., and J. B. McBride, T.D., with permission to wear the prescribed uniform, E. T. Vint, F. R. Humphreys; Captains W. Smartt, J. Brown, J. M. Benson, A. MacLennan, W. E. Lec, R. H. Shaw, G. H. Jones, C. A. Ensor, J. Muir.

DIARY OF SOCIETIES AND LECTURES.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.—Mon., 8.30 p.m. Papers:—Dr. F. J. Poynton and Dr. J. W. McNeo: A Case Resembling Leukaemia, but Presenting Unusual Clinical and Pathological Features, with Specimens and Slides. Mr. T. H. Kellock: A Method of Treating Abscesses. Dr. W. Broadbent: Observations on Heart Disease.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Mon., Wed., and Fri., 5 p.m. Hunterian Lectures by Sir Arthur Keith: The Facial Characteristics of Living Races of Mankind.

ROYAL SOCIETY OF MEDICINE.—Section of Odontology: Mon., 8 p.m. Mr. S. Munnery: Mandibular Sarcoma in an Infant. Mr. Montagu Hopson: Maori Skull of Dental Interest. Mr. Douglas Gabbell: Misfit of Dentures due to Vulcanite and some Remedies. Section of Medicine: Tues., 5 p.m. Discussion on the Diagnosis of Gastric Ulcer. Speakers: Dr. C. Bolton, Sir Cuthbert Wallace, Dr. Ryffel, Dr. A. E. Barclay, and Dr. W. Gordon. Social Evening: Wed., 8.30 p.m. Reception by the President and Lady Bland-Sutton; 9 p.m. Address by Professor Elliot-Smith on the Rhodesian Skull. The Library will be open and various objects of interest will be exhibited. Music, light refreshments, and smoking. All Fellows and their friends are cordially invited; no tickets are required. Fellows who know of Dominion and foreign practitioners visiting this country are asked to send their names and addresses to the Secretary in order that invitations to attend the social evenings may be sent to them. Section of Urology: Thurs., 8.30 p.m. Pathological and Clinical Evening: Cases and Specimens. Section of Study of Disease in Children: Fri., 4.30 p.m. Cases. Section of Epidemiology and State Medicine: Fri., 8 p.m. Paper:—Dr. S. Monckton Copeman, Dr. R. A. O'Brien, Dr. A. J. Eagleton, Mr. A. T. Glennay: Experiences with the Schick Test and Active Immunization against Diphtheria.

POST-GRADUATE COURSES AND LECTURES.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION, Royal Maternity and Women's Hospital.—Wed., 4.15 p.m., Dr. J. H. Martin: Obstetrical Cases.

MANCHESTER ROYAL INFIRMARY.—Tues., 4.30 p.m., Mr. J. H. Ray: General Management of Fractures.

MANCHESTER: ST. MARY'S HOSPITALS, Whitworth Street West Branch.—Fri., 4.30 p.m., Dr. Fothergill: Post-menopausal Atrophic Conditions.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland Street, W.1.—Daily, In- and Out-patient Attendances: Mon., 5.30 p.m., Lecture by Dr. Parkinson: Dropsy.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C.1.—Mon., Tues., Thurs., and Fri., 2 p.m. Out-patient Clinics: Tues. and Fri., 9 a.m., Surgical Operations. Lectures: Mon. (noon), Dr. Greenfield: Cerebro-spinal Fluid; 3.30 p.m., Dr. Walshe: Afferent Paths and Effects of Lesions thereon. Tues., 3.30 p.m., Dr. Risien Russell: Sciatic Neuritis. Thurs., 3.20 p.m., Dr. Kinnier Wilson: Pathogenesis of Involuntary Movements. Fri., 3.30 p.m., Dr. Collier: Vascular Disease of the Nervous System.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell Square, W.C.—Wed., 4 p.m., Dr. A. C. Inman: Laboratory Aids to the Diagnosis of Tuberculosis Infection.

SALFORD ROYAL HOSPITAL.—Thurs., 4.30 p.m., Mr. Jefferson: Some Remarks on the Syndrome of Cerebral Compression.

ST. JOHN'S HOSPITAL, 49, Leicester Square, W.C.—Thurs., 6 p.m., Chesterfield Lecture by Dr. W. K. Sibley: Alopecia and its Treatment.

WEST LONDON POST-GRADUATE COLLEGE, Hammersmith, W.—Daily, 10 a.m., Ward Visits; 2 p.m., In- and Out-patient Clinics and Operations. Mon., Dr. A. Saunders: Gall Stones. Tues., of the Breast; Wed., Dr. Burnford: B coli. A. Baldwin: Rectal Surgery. Fri., Dr. Burrell: Artificial Pneumothorax.

British Medical Association.

OFFICES AND LIBRARY, 429, STRAND, LONDON, W.C.2.

Reference and Lending Library.

THE READING ROOM, in which books of reference, periodicals, and standard works can be consulted, is open to members from 10 a.m. to 6.30 p.m., Saturdays 10 to 2.

LENDING LIBRARY: Members are entitled to borrow books, including current medical works; they will be forwarded, if desired, on application to the Librarian, accompanied by 1s. for each volume for postage and packing.

Departments.

SECRETARY AND BUSINESS MANAGER: Mr. J. G. Gerrard, 429, Strand, London, W.C.2.

EDITOR, *British Medical Journal* (Telegrams: Alotogy, Westrand, London).

Telephone number for all Departments: Gerrard 2630 (3 lines).

SCOTTISH MEDICAL SECRETARY: 6, Rutland Square, Edinburgh. (Telegrams: Associate, Edinburgh. Tel.: 4357 Central.)

IRISH MEDICAL SECRETARY: 16, South Frederick Street, Dublin. (Telegrams: Bacillus, Dublin. Tel.: 4737 Dublin.)

Diary of the Association.

JANUARY.

- 24 Tues. Lewisham Division, Farnboro' House, Kirkdale, Sydenham, S.E.26, 8.45 p.m.
London: Office Committee, 10.30 a.m.
London: Organization Committee, 2 p.m.
- 25 Wed. London: Medico-Political Committee, 2.30 p.m.
- 25 Thurs. London: Insurance Acts Committee, 2.30 p.m.
London: Journal Committee, 2.30 p.m.
Warrington Division, Dinner.
- 27 Fri. London: Public Health Committee, 3 p.m.
- 31 Tues. Bedford Division, Bedford County Hospital, 3 p.m.

FEBRUARY.

- 1 Wed. London: Finance Committee, 2.30 p.m.
Shrewsbury: Welsh Committee.
South Middlesex Division, St. John's Hospital, Twickenham.—8 p.m., Business Meeting; 8.45 p.m., Paper by Dr. H. Batt's Shaw: Early Diagnosis of Tuberculosis.
- 7 Tues. Kingston-on-Thames Division, Surbiton Cottage Hospital, 8.30 p.m.: Address by Mr. J. Cunningham on Some Conclusions in Abdominal Surgery.
- 8 Wed. Chesterfield Division, Dinner.
Lancaster Division: B.M.A. Lecture by Dr. T. Eastham, on "Medical Men and their Legal Difficulties."
West Dorset Division, Dorchester, 2.30 p.m.—B.M.A. Lecture by Dr. J. S. Fairbairn: What disability is caused by and what treatment is required for internal displacement?
- 10 Fri. East Yorks Division, Hull.—B.M.A. Lecture by Sir Frederick Mott: The Reproductive Organs in Relation to Mental Disorders.
South Essex Division, Hotel Victoria, 8.15 p.m.: Paper by Dr. F. W. Price on Recent Advances in the Diagnosis, Prognosis, and Treatment of Heart Disease.
- 15 Wed. Council.
- 16 Thurs. North Suffolk Division, Lowestoft: Address by Medical Secretary.
- 17 Fri. Edinburgh Branch: Winter Clinical Meeting and Dinner.
- 21 Tues. Croydon Division, Croydon General Hospital.—Dr. J. Bright: Banister: Obstetrics and Gynaecology, 8.15 p.m.
- 22 Wed. Mid-Essex Division, Chelmsford: Address by Medical Secretary.

MARCH.

- 1 Wed. South Middlesex Division, St. John's Hospital, Twickenham, 8 p.m., Clinical Meeting.
- 7 Tues. Kingston-on-Thames Division, Surbiton Cottage Hospital, 8.30 p.m.: Address by Dr. Wm. Brown on Psychology and Psychotherapy.

APPOINTMENTS.

HAWORTH, J. K., M.D., M.S.Durh., Medical Superintendent at St. Mary's Hospital, Paddington.

EDINBURGH ROYAL INFIRMARY.—The following resident, etc., appointments have been made:—Resident House-Physician: A. R. Wightman, M.B., Ch.B., to Dr. Chalmers Watson. Resident House-Surgeons: G. Flint, M.B., Ch.B., to Sir David Wallace; D. S. Middleton, M.B., Ch.B., to Professor Thomson; S. C. Atcock, L.R.C.P. and S.E., L.R.F.P. and S.G., to Mr. Scot-Skiving; K. B. Williamson, M.B., Ch.B.; H. Radford Potter, M.B., Ch.B.; and C. Mackay Seward, M.B., Ch.B., to surgical out-patient department. Mr. Pirio Watson, Non-resident House-Surgeon: R. J. O. Taylor, M.B., Ch.B., to Mr. Lees. Clinical Assistants: Miss Dorothy Mitchell, M.B., Ch.B., to Dr. J. S. Fraser; N. S. Whitton, M.B., B.S., and S. Young, M.B., Ch.B., to Dr. J. S. Fraser; G. M. Shaw Smith, M.B., Ch.B., D.P.H., to Mr. Lees.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

DEATHS.

LAWRENCE.—On December 9, Dr. Jas. Lawrence, late of Darlington, passed away at Westward Ho, North Devon, whither he had retired rather more than two years ago.

MARSHALL.—At 1, Douglas Crescent, Edinburgh, on the 12th inst., Elizabeth Mackie, wife of Lieut.-Colonel G. Marshall, I.M.S.(ret.).

O'KEEFE, Thomas Francis, Surgeon Commander R.N.(ret.), December 23rd, 1921, at a nursing home in Richmond, aged 47.

RUTHERFORD.—On January 2nd, at the Royal Infirmary, Manchester, Andrew Adams Rutherford, M.D., LL.D., of Buxton.

in compressed tablets, and in ampoules containing 3 per cent. of the powder in solution. The precautions which should be observed in administering the preparation are indicated on a circular which, we understand, accompanies each package. Coagulen-ciba is made by the Society of Chemical Industry in Bale, Switzerland, and is supplied in this country by the Clayton Aniline Company, 68½, Upper Thames Street, London, E.C.4.

Tuberculous Egg Prepared Antigen.

Tuberculous egg prepared antigen is, it is stated, prepared by the process devised by Professor Besredka. In this method tubercle bacilli are grown in a nutritive medium of which the basis is yolk of egg. The four days old culture is killed by heat, diluted with sterile water, and an emulsion formed. The sero-diagnosis of tuberculosis is carried out according to a technique very similar to that of the Wassermann reaction for syphilis; the emulsion of dead tubercle bacilli is used as the antigen in the reaction. It is claimed that in cases of established tuberculosis the reaction is constantly positive, and that in cases of suspected tuberculosis a positive reaction renders the presence of that infection very probable. The exact clinical value of this reaction is still a matter of uncertainty. The preparation is sent out in sealed phials of 3 c.cm., and the manufacturers state that it will keep indefinitely. The agents in this country are the Sealand Trading Company, Buchanan Buildings, 24, Holborn, London, E.C.1.

MEDICAL AND SURGICAL APPLIANCES.

Electroscope and Endoscopic Tubes.

DR. IRWIN MOORE (London, W.) has designed combined electroscope and endoscopic tubes in order to simplify the technique and armamentarium for direct laryngo-tracheo-bronchoscopy and oesophagoscopy, and to reduce the difficulties met with in the exploration of the bronchi and oesophagus.

The important feature, he writes, is that both proximal and distal lighting is combined in one instrument, and that interchange is possible whilst the endoscopic tube is *in situ*, without disturbing its position. The electroscope is drawn, at the same time, into the endoscopic tube, and the intensity of light for illumination is obtained with tubes of large diameter. By a simple turn of the screw which fixes the lamp shaft to the arm, the entire illuminating portion of the apparatus may be removed or replaced. Since the handle contains no mechanical or electrical connexions, as in the Brunings pattern, it may be readily boiled and sterilized. The advantages of the apparatus are obvious. The mechanism allows of the easy passage and free manipulation of instruments under direct inspection, without obstructing the field of operation; again, if the patient coughs, the mirror may be instantaneously switched out of the way, and therefore is not soiled by coughed-up material. Also, by dispensing with the mechanism by means of which the handle is rotated from side to side in Brunings's instrument, displacement of the distal end of the endoscopic tube, which frequently occurs, is prevented. The main principle on which these endoscopic tubes is designed is the same as that of the Chevalier Jackson tubes, but they are made of a size corresponding to the diameter of the larger tubes of Killian, Brunings, and Chevalier Jackson. Passing down the inside of the tube is an open half-circular slot for the passage of the distal lighting carrier. In this way the light carrier is out of the way of instruments, and there is no reduction in the inside diameter of the tube.

The apparatus has been made by Messrs. Mayer and Phelps, New Cavendish Street, W., to whom Dr. Moore desires to give credit for surmounting the mechanical difficulties. Full particulars can be obtained from the makers.

A Simple Aspirator.

Mr. H. O. GUNWARDENE, M.B., B.S. (Clinical Assistant, National Hospital for Diseases of the Heart), writes: Having felt the want of a simple aspirator I have, in conjunction with an engineer friend, Mr. B. O. W. Cantrell, designed a combined aspirating syringe and trocar, shown in the illustration, and used it in place of the ordinary aspirator.

The disadvantages and difficulties attending the use of the ordinary aspirator are well known; with the combination instrument depicted there is no rubber connexion to become perished and no valves to get out of order. The instrument may be used as a simple syringe for exploring, and it can also be used as a siphon for aspirating. It is convenient to carry, easy to sterilize and manipulate. It consists of a large "Record" type of syringe with trocars and cannulae of various sizes, and has been made by Messrs. Allen and Hanburys, 48, Wigmore Street, London, W.1.

THE WORK OF THE MEDICAL RESEARCH COUNCIL, 1920-21.

SECOND NOTICE.]

In dealing last week (p. 74) with the report of the Medical Research Council for 1920-21, attention was directed especially to the work of the National Institute for Medical Research. We will now attempt to give some account of the research schemes in specific subjects carried out at various centres, but the task is much more difficult, because to enumerate all the many and various inquiries, experimental and clinical, subsidized or directed by the Council, would be to compile a list of nearly all the subjects with which progressive clinical medicine is at present concerned. We can only pick out a few topics which may afford the reader a general idea of the many directions in which the Council is giving assistance.

Vitamins.

The inquiries into the nature and effects of accessory food factors, still conveniently termed "vitamins," although the theory on which the work was formed has been abandoned, have been continued during the year under the direction of a special committee appointed jointly with the Lister Institute of Preventive Medicine. The chairman of the committee is Professor Gowland Hopkins, and its members are Dr. Drummond, Professor Harden, F.R.S., Mr. W. B. Hardy, F.R.S., Dr. A. W. J. MacFadden, C.B., of the Ministry of Health, Professor C. J. Martin, F.R.S., Director of the Lister Institute, and Professor Edward Mellanby, now of Sheffield, with Dr. Harriette Chick as secretary. During Miss Chick's absence in Vienna Professor Harden has acted as secretary. The total annual expenditure of the Council under this head is nearly £10,000.

Under Professor Harden's direction, Dr. S. S. Zilva, working with Dr. Miura at the Lister Institute, has made quantitative estimations of the fat-soluble factors and has studied the very high potency in this respect of cod-liver oil; they have also carried out experiments on the diffusion of the antiscorbutic and antiscorbutic factors through membranes of varying permeability, with a view to obtaining indirect evidence of the size of the molecules of the vitamin substances. Experiments suggest that the destruction of the vitamin at the temperature of boiling water is due rather to oxidation than to the direct action of heat. Dr. Zilva has continued with Dr. H. Schütz his study of the influence of deficient nutrition on resistance to disease, and, in conjunction with Professor Harden, has confirmed the absence of the antiscorbutic factor in fresh beer, but has demonstrated that yeast can synthesize the antiscorbutic factor. Dr. Drummond and Dr. Zilva are inquiring into the nutritive values of different commercial oils and fats; in addition to studying the process of manufacture in many factories in this country and on the Continent they paid a special visit to the Norwegian cod-liver oil industry. The results of this inquiry have immediate practical applications to the industry, and have been communicated to the Government of Newfoundland. They have thrown light also upon questions of general biological and geographical interest.

The work done by Professor and Mrs. Mellanby at Cambridge and Sheffield has been the subject of special reports, the last of which was noticed at length in our issue of January 7th (p. 20). At Cambridge Professor F. G. Hopkins has continued his investigations into the nature and properties of vitamin A; they have led indirectly to the acquisition of fresh facts with regard to the mechanism of oxidation in living tissues. Dr. C. Da Fano has continued at King's College his investigations into the structure and pathology of the ductless glands and the nervous system in deficiency diseases. The expenses of the clinical inquiry as to deficiency diseases in Vienna, carried out by Miss Chick and her colleague, have been borne jointly by the Medical Research Council and the International League of Red Cross Societies. It is hoped that a full report of the results of the work will soon be available; meanwhile preliminary reports on different departments of the subject have been published in our columns, the last being the paper by Drs. Harriette Chick and E. J. Dalyell on the influence of food's rich in

accessory factors in stimulating development in backward children, published in these columns on December 24th, 1921, p. 1061.

Rickets.

Under the direction of Professor C. J. Martin, Dr. E. M. Luce has studied the relation of calcium metabolism to the parathyroid and sexual glands. Erdheim and Korenchevsky have alleged that the parathyroids become hypertrophied in spontaneous cases of rickets in animals. Dr. Luce has studied the condition of these glands in rats in which rickets has been produced by diets deficient in calcium and in vitamin A; he has observed an increase in size without any unusual character in the cells. Erdheim has stated that rickets follows loss of the parathyroid glands in rats. But Professor Korenchevsky, who receives a whole-time grant, has made experiments on this line at the Lister Institute, and, provided due attention was given to the diet of the animals (a factor which appears to have been neglected in the original studies), his results have always been negative. In a series of experiments on the part played by diet in the causation of rickets in rats, he first gave a simple diet on which the animals remained healthy and grew well, producing abundance of healthy offspring, and then observed the influence of various conditions, including modifications of diet, in the case of both young and adult animals. Before the conclusion that rickets had been produced in any given case was accepted rigid conditions were enforced, involving a great number of chemical analyses and histological examinations.

"Confinement in small cages was not found to produce rachitic conditions, and negative results were obtained from attempted infection with live cultures of *B. parfringens*, *B. sporogenes*, and *B. bifertmentsans*. Conditions similar to rickets were produced by dietetic deficiency of calcium alone and of vitamin A alone, and most readily in the absence of both these substances; the changes were most marked in young rats where the mother had also been similarly dieted during pregnancy."

Tuberculosis.

The problem of tuberculosis is being attacked by a number of workers in different places. There are subcommittees on phthisis in relation to occupations, on tuberculin, and on the bacteriology of tuberculosis, but in no instance is it possible to do more than make a progress report.

Professor S. L. Cummins has been investigating, with the assistance of Miss C. M. Acland, the applicability of Kliene's "opsonic end-point" to the early diagnosis of tuberculosis. Experiments which were begun at the Royal Army Medical College and the Brompton Hospital Sanatorium are now being conducted in the laboratories of the Welsh National Memorial Association at Cardiff and at the Glan Ely Hospital. Some points of great interest with regard to the natural mechanism of self-protection against tuberculosis have been noted. It appears that the specific chemical substances which arise to aid phagocytosis act rather by increasing the activity of the phagocytes than by opsonizing or sensitizing the bacilli. The experiments afford some support of the earlier work of Sir William Leishman on stimulins.

Dr. A. Stanley Griffith, at the Cambridge Field Laboratories, has continued his study of the bacteriological characteristics of tubercle bacilli from different sources—lupus, abdominal tuberculosis, and tuberculosis of bones and joints. The human and bovine cultural types have been differentiated and their virulence investigated. With Sir Leonard Rogers, Dr. Griffith has estimated the curative effects of sodium morrhuate, sodium soyate, and sodium gynocardate, all of which have been found beneficial in leprosy. The results in tuberculosis were negative. In cultural experiments the first two drugs were found to favour the growth of the tubercle bacillus and the third to inhibit it. The inquiry at the Brompton Hospital into the value of artificial pneumothorax has advanced so far that Dr. Burrell, with the assistance of Dr. A. S. MacNalty, is now engaged in preparing a report upon the whole investigation, which includes the collation of the results of over a hundred cases.

Dr. A. Rowand is continuing his study of the early symptoms of disease in children, with special reference to tuberculosis; he has the advantage of working at the St. Andrews Institute for Clinical Research under the direction of Sir James Mackenzie, and of the collaboration of the members of the institute staff, and of the help of all the practitioners in the town. The scheme is designed to keep under observation all the children in St. Andrews from birth onwards; special attention is being paid to the appearance of palpable glands during infancy, to exhaustion and its

value as an early symptom, to the conditions associated with the earliest appearance of enlarged tonsils or of adenoids, and to the effect of the diets in common use on failure of health and on the development of impaired digestion in later years. X-ray examinations of the chest in healthy children are being made at an early age to determine the prognostic significance of root shadows as revealed by the subsequent histories.

Dr. H. K. Ward, who receives a whole-time grant and works under the direction of Professor Dreyer at Oxford, has attempted to standardize degrees of tuberculous infection and to produce a standard tuberculin. Professor C. H. Browning, with the help of Miss Gulbransen and Miss Meldrum, has made further investigations into the behaviour of different strains of tubercle bacilli in experimental infections, and the work, upon which a report will shortly be published, has been carried far enough to enable a beginning to be made with experimental tests of the curative values of various compounds.

Grants to the King Edward VII Sanatorium at Midhurst, to Brompton Hospital Sanatorium, and the Peamount Sanatorium near Dublin, for the collection of records of the after-histories of sanatorium patients, have been continued, and a supplementary grant was made to Midhurst for the collection of the family histories of 300 patients and of collation of the records of ten years' work by Sir St. Clair Thomson on laryngeal tuberculosis.

At St. Bartholomew's Hospital, London, Dr. R. G. Canti and Dr. G. L. Lyon-Smith, both receiving part-time grants, have made preliminary investigations in the hope of devising a rapid and efficient practical method of recognizing the tubercle bacillus in milk without recourse to animal experiments. A collection has been made of the different acid-fast bacilli liable to be confused with *B. tuberculosis*, and methods of differential staining are being studied. At the University of Liverpool Professor J. M. Beattie, with the help of Mr. F. C. Lewis, is continuing his experiments on the electrical sterilization of milk. A report was published last year, but further experiments are being carried out with regard to the thermal death point of bacteria in stationary and moving columns of milk, and on the relative efficiency of the electrical method and of the application of external heat under similar conditions.

Disseminated Sclerosis.

Investigations begun by Dr. Gye as long ago as 1912 show that disseminated sclerosis can be communicated by the injection into rabbits of the cerebro-spinal fluid from a rapidly progressing case. His early results were confirmed by other workers, and have been amplified by his fresh series of experiments; which have recently been reported in *Brain*.

At the University of Glasgow the investigation of the etiology and treatment of the disease is being continued by Dr. D. K. Adams, who has the assistance of Drs. E. M. Dunlop, J. W. S. Blacklock and Wilfred Scott. The results so far obtained are against the theory of syphilitic origin; the colloidal gold reaction appears to be constantly positive. Prolonged courses of treatment with neosalvarsan have given favourable results. Dr. Adams related some of the results of his inquiry to the Section of Neurology and Psychiatry at the annual meeting in Newcastle. His paper was published in our columns of November 19th; to this we may refer readers for further information.

Radiotherapy.

The large amount of 5 grams of radium bromide, recovered from military uses, was entrusted by the Government to the Council for medical research purposes, and was lent in the first instance to the Middlesex Hospital for initial experiments and therapeutic trials. A report will shortly be published by the Council. The chief results of the clinical work was to show that by superficial applications of the radium a number of inoperable cases of malignant disease had been rendered operable. Application of a dose of radiation which did not seriously damage the skin was followed by temporary disappearance of the growth, but recurrences frequently occurred after a few months unless the exposures were repeated. In order to obtain uniform irradiation surface applications should be combined with the surgical insertion of radium.

The whole amount of radium bromide at the disposal of the Council has now been divided into a number of parts; this has been done at the National Physical Laboratory after

a due period of stabilization by Professor Sidney Russ and Mr. F. Harrison Glew. Certain quantities have now been granted on loan to the Middlesex Hospital, University College Hospital, King's College Hospital, St. Bartholomew's Hospital, the London Hospital, and the Radium Institute; to the General Hospital, Birmingham, to King Edward VII Hospital, Cardiff, and to the Royal Infirmary, Aberdeen. The Irish Public Health Council in Dublin has also received a portion, and is organizing a local scheme of distribution. At each centre special attention is being concentrated upon a particular form of malignant disease and its treatment, and each centre will make a yearly report. In selecting the centres regard has been had to the facilities for pathological work in the study of the many problems that confront the radiologist.

Experiments have been carried out at the Middlesex Hospital by Professor Russ and Dr. Chambers on certain effects of x rays; they indicate broadly that the reaction in a patient may not depend only upon the cellular changes occurring in the tumour mass itself, but also upon the effects of the rays upon various processes seated in normal tissues. The results are in many respects parallel to those obtained at the Rockefeller Institute, New York. "The possibility of stimulating instead of killing cancer cells by an insufficient dose of radiation," the report continues, "has already been shown experimentally, and it is clear that in the radiological treatment of malignant disease we are confronted with a balance of forces of which the nature in detail can only be revealed by further investigation."

A grant has been made to the Radium and X-ray Workers' Protection Committee to enable Dr. J. C. Mottram, of the Radium Institute, to examine the blood in normal persons and in persons exposed to radiation.

ASYLUM ADMINISTRATION.

A MEMORANDUM, appropriately headed by the motto, "*Judi alteram partem*," has been issued by the Mental Hospitals' Association¹ as a reply to the numerous criticisms of asylums in this country. This association is composed of the visiting committees of public asylums, and it is thus particularly well fitted for the task it has undertaken. Comprising as it does the elected representatives of the ratepayers who are called upon to govern asylums, the association has a more intimate knowledge of the economic position and general conditions of these institutions than any other section of the public. The views expressed in this pamphlet carry weight and merit careful consideration. In the introduction the writers draw attention to the improvements which have taken place in the care of the insane poor during the last thirty years; it is pointed out "that since the passing of the Lunacy Act, 1890, the conditions have been vastly altered for the better. The old barrack-like buildings in which the insane poor were herded together have all been improved, in instances beyond recognition, and the true hospital or healing spirit is enlivened in these institutions, by management and staff alike, to an extent which was never dreamed of thirty years ago." The steady progress in the care of the insane which is thus described can scarcely be disputed, and it is probably true to say that the average standard of comfort in British asylums exceeds the average of that found in any other country. It is otherwise as regards the progress of psychiatry as a science, and we have much to learn from other countries in this respect. In 1914, when the war broke out, the Board of Control, the visiting committees, and the Medical-Psychological Association were fully alive to the necessity for organized research and facilities for teaching. The pamphlet makes this evident in outlining the work of the Mental Hospitals' Association in endeavouring to further improved methods for the treatment of incipient insanity, and a conference of visiting committees in the year 1912 resulted in certain small grants being made from the Imperial Exchequer through the Board of Control in aid of research work. The grants are now consolidated and administered by the Medical Research Council. There is a significant gap in the activities of the committees as a collective body until 1918, when the pamphlet records the actual formation of the Mental Hospitals' Association. In

the interval the war had broken out, with the result that the hopes and ambitions of asylum workers were frustrated, and regression rather than progress was inevitable. Little reference is made in the pamphlet to the war period, when asylums were carried on under conditions of the greatest difficulty. The writers might well have done so if their chief aim had been the refutation of the specific charges levelled recently against asylum management, since these have referred in a large measure to abnormal conditions which could, at the time, scarcely be remedied. A constructive policy is outlined in this pamphlet, and this we feel to be of much more value than a detailed reply to criticisms would have been.

The writers point out that while improvements have been made in the care and treatment of the insane, the asylum committees have felt for some time past that a wide field for further ameliorations still exists. Reforms are suggested in the following directions: (1) Increased grants for research; (2) amendment of the lunacy laws, in order that incipient cases of mental illness may be treated before the malady has reached such an advanced stage as to compel the certification and detention of the patient in an asylum; (3) power to receive voluntary boarders in public asylums; (4) the creation of out-patient departments; (5) an increased grant from the Exchequer in aid of the cost of maintaining patients in asylums; (6) the elimination of the taint of pauperism. With these suggestions we are in entire sympathy, and they are clearly indicative of a progressive and enlightened policy on the part of the asylum committees of this country.

A detailed scheme is outlined for the treatment of early cases of mental disorder which deserves careful consideration. As an immediate solution of the difficulty of securing suitable accommodation for the treatment and study of early cases it is suggested that seven or eight asylums, situated as near as possible to populous centres possessing good general hospitals with medical schools, might be evacuated, as was done when certain asylums were converted into war hospitals and utilized for the treatment of mental ailments free from any connexion with the lunacy laws. This proposal has much to commend it, but we observe an absence of any reference to the difficult question of power of detention. We feel that this subject cannot be ignored in view of the lack of insight which the subjects of a true psychosis so frequently exhibit. They may feel themselves wronged, persecuted, or unusually happy and vigorous, but on the whole they do not regard themselves as ill, and they have, in consequence, no wish to be treated or detained in a hospital. Yet many of these early cases are highly irresponsible and liable to perform antisocial acts, and it would thus appear that some form of detention against the wish of the patient may be required in some cases if the clinic is to serve its complete social function. It is, of course, useless to cite the fact that soldiers were treated during the war for mental disorder without any form of certification, as they were under military discipline and were not in a position to leave the hospital if they wished to do so.

The views expressed by the Mental Hospitals' Association cannot fail to exert a beneficial influence by enlightening the public as to the work of their representatives on behalf of the insane; their publication at this moment is opportune in view of the conference the Board of Control is holding this week with the representatives of the visiting committees and medical staff of the asylums, since it reveals an earnest desire to improve the conditions under which the insane are treated. Ultimately, as stated in the introduction to this pamphlet, "it rests entirely with the public as to what, if any, better conditions should prevail in connexion with the treatment and care of the mentally afflicted."

A JOURNAL with the title *Le Maroc médicale* is to be published at Casablanca, Morocco, under the editorship of Dr. E. Speder.

DR. J. MORTON HOWELL, of Dayton, Ohio, has been appointed diplomatic representative and Consul-General for the United States to Egypt.

THE *Malthusian*, a monthly journal published for the last forty-five years by the Malthusian League, is to be replaced this month by a monthly publication to be called *The New Generation*. Its general policy will be to advocate "early marriage combined with rational birth control."

MR. WILLIAM C. REID, of Edinburgh, who died on December 23rd, 1921, has left a total of £63,000 to charities, including £8,000 to Edinburgh Royal Infirmary, £8,000 to the Longmoor Hospital for Incurables, Edinburgh, and £5,000 to the Royal Victoria Hospital for Consumption, Edinburgh.

British Medical Journal.

SATURDAY, JANUARY 21st, 1922.

THE SOURCES OF VITAMINS.

THE composition, origin, and action of vitamins have been the subject of a very large amount of research during the past few years. Progress has of necessity been slow, for the subject presents difficulties which are almost unique. Vitamins are very unstable bodies of unknown chemical composition: they occur in minute quantities, and the only way in which their presence or absence can be proved is by animal-feeding experiments lasting several weeks. These characters represent a cumulation of difficulties which renders quantitative work of even approximate accuracy extremely difficult. Though the chemical nature of vitamins is still unknown recent researches have thrown light on the conditions under which they are formed. It is generally recognized that mammals are unable to synthesize vitamins and are entirely dependent upon the supplies which they obtain either directly from vegetables or at second hand from the flesh or milk of other animals.

It has generally been assumed that plants can synthesize vitamins, but doubt has been cast upon this by various workers. Bottomley stated in 1916 that certain plants obtained these accessory food substances from the growth of certain organisms in the soil. Recently Williams and other workers have gone further and have claimed that vitamins, and especially the water-soluble vitamin B, are necessary for the growth of yeast and other micro-organisms. These statements made it very difficult to conceive where and how the vitamin supply of the world was produced. Fortunately recent work has cleared up this question. Nelson, Fulmer, and Cessna¹ grew yeast for a year on a medium composed of inorganic salts and cane sugar: they made subcultures every other day, and calculated that the final solution only contained 1×50^{-180} of the original constituents of the medium or yeast. This yeast thus grown on a synthetic diet was found to contain a normal amount of vitamin B. Harden and Zilwa² also showed that yeast grown on a pure synthetic diet contained almost as much vitamin B as yeast grown under normal conditions.

These experiments seem fully to establish the contention that yeast can grow freely without any supply of vitamins, and that it can synthesize vitamin B from a diet of inorganic salts and sugar. Yeast does not synthesize the fat-soluble vitamin A, but the origin of this vitamin appears to have been demonstrated by recent experiments of Coward and Drummond.³ These observers showed that dried seeds contained little vitamin A, and that this amount was not increased by germination, but that as soon as the seeds formed green leaves a considerable amount of vitamin A appeared. Experiments made with *Tradescantia* shoots grown on Sachs's solution also showed that green plants could synthesize vitamin A from inorganic salts. The production of vitamin A was shown to be dependent upon the presence of chlorophyll in plants, for etiolated seedlings contained no vitamin A, nor did white leaves from the interior of cabbages. In green seaweeds, containing chlorophyll, vitamin A was present, but red seaweeds contained none. Mushrooms were found to be almost completely

deficient in vitamin A. It appears, therefore, that the presence of chlorophyll is essential for the synthesis of vitamin A, and that chlorophyll-containing plants can synthesize vitamin A when fed on a pure synthetic diet.

The chemical nature of vitamin A is still unknown. Coward and Drummond found that it could be extracted by fat solvents from green leaves and that it appeared in that fraction of the fat which is resistant to saponification. Vitamin A was at one time believed to be one of the yellow plant pigments. These plant carotinoids are the source of the lipochromes which produce the yellow colour of animal fat, and, as a general rule, those animal fats which contain most lipochrome also contain most vitamin A. Various workers have shown, however, that this association is not constant and that the association between lipochromes and vitamin A is probably accidental.

These researches give a fairly clear picture of the vitamin exchange in living organisms. Vitamin B is synthesized by all forms of plant life, whilst vitamin A is only synthesized by plants containing chlorophyll. Fishes and whales obtain the rich supply of vitamin A present in their oil either directly or indirectly from the chlorophyll-containing algae or from the chlorophyll-containing organisms in the plankton. Land animals derive their vitamin A supply from the green vegetables.

The source of the vitamin A in milk has been shown very clearly by Drummond, Coward, and Watson.⁴ They measured the vitamin content of the milk of a herd of cows from April to July, 1921. The animals were stall fed until the end of April, and in April their milk contained little vitamin A; after the cows had been a week at grass their milk yielded a high content of vitamin A, which persisted during May and June. The drought last year spoiled the pasture, however, so that in July the cows had to be fed on cake, and the vitamin A content of the milk at once dropped. A quantitative study of the vitamin A content of butter showed that during the process of butter making a certain amount of vitamin A disappeared, but that butter could be stored in tins for many months without any marked diminution in vitamin content. The conclusion was drawn that the vitamin A content of butter was much more dependent upon the season at which the butter was made than upon the length of time for which it had been stored. This conclusion is obviously of great practical importance. The cow can only secrete in its milk the vitamins which it receives in its food, and the milk or butter of a cow fed on a vitamin-poor diet will contain very little vitamin. Our knowledge of the importance of vitamins has emphasized the necessity for obtaining fresh milk in which the vitamins have not been destroyed, but now it appears that it is equally important to obtain milk from a cow receiving a vitamin-rich diet. Drummond and his fellow workers have examined also the vitamin A content of the body fats of animals, and in this case also they found that the fat of a stall-fed animal often contained very little vitamin A; whilst, on the other hand, the fat in tinned beef obtained from grass-fed animals was often rich in vitamins after many months' storage. These conclusions as regards the vitamin content of tinned foods apply only to fats which have been stored under good conditions, and are probably true only for the case of vitamin A, which is more stable than either vitamin B or C.

It is, of course, a matter of extreme difficulty to preserve vitamin C: the only substances in which this vitamin is preserved for any length of time are the fruit juices, and even from them the vitamin slowly disappears. Harden and Robison⁵ found that when dried orange juice was stored in a desiccator for fifteen months it lost 50 per cent. of its vitamin C content, and dried

¹ Nelson, Fulmer, and Cessna, *Journ. of Biol. Chem.*, 77, xiv, 1921.

² Harden and Zilwa, *Biochem. Journ.*, 433, xv, 1921.

³ Coward and Drummond, *Biochem. Journ.*, 530, xv, 1921.

⁴ Drummond, Coward, and Watson, *Biochem. Journ.*, 540, xv, 1921.

⁵ Harden and Robison, *Biochem. Journ.*, 521, xv, 1921.

orange juice kept under ordinary conditions lost 85 per cent. of its activity. The supply of vitamin A and vitamin C therefore appear to present two separate problems. In the normal adult there is really no problem, for an adequate quantity of green vegetables in the diet provides a full supply of all three vitamins. In the case of bottle-fed babies, however, the supply of vitamin A appears to depend chiefly upon the diet on which the cows supplying the milk are fed, while the supply of vitamin C is determined chiefly by the treatment which the milk undergoes during its passage from the dairy to the infant. The conclusions of Coward and Drummond certainly suggest that during the winter it is desirable to add cod-liver oil, or some other rich source of vitamin A, to the food of infants on a milk diet.

EDUCATION AUTHORITIES AND SCHOOL MEDICAL OFFICERS.

THE consolidated regulations for special services of elementary education, made by the Board of Education in 1920, direct that a local education authority "shall appoint a school medical officer, who will be responsible to the [Education] Authority for the efficient carrying out of any arrangements made by the Authority for the medical inspection, supervision, and treatment of children of elementary school age within their area, and also for the discharge of such other duties as may be from time to time assigned to him"; and that "the Authority shall annually submit to the Board a report from their school medical officer describing and tabulating the work of himself and his staff during the 12 months ending 31st December." It is further laid down that the records required by the Board must be available for examination by the Board's inspectors, and the term "inspector" is defined to mean "exclusively one of His Majesty's Inspectors of Schools, one of the Medical Officers of the Board, or any other persons employed by the Board for the purpose of inspection."

Throughout these regulations there is no reference to the functionary employed by many of the larger local education authorities, and described in some areas as the "secretary of education," in others as the "director of education," and in others again as "secretary to the education committee" or "chief education officer." Since the passing of the Education Act of 1902 special appointments of this kind have been made by an increasing number of authorities, including most of the county councils. Such posts are not statutory; but the persons holding them are now numerous enough to have formed themselves into an association, and self-important enough to have drawn up a memorandum laying down what they conceive to be the relations which should subsist between the school medical service and the general educational administration, of which they evidently regard themselves as the keystone. According to our information, this document attempts to lay down the principle that in each area the school medical service—essentially a health service—should be placed under a lay official, the secretary or director of education.

The Board of Education, as we have said, directs that the school medical officer shall be responsible to the local education authority, and that the authority itself shall submit his report to the Board. This, however, does not go far enough to suit the Association of Secretaries and Directors of Education, which prefers to ordain that "the chief function of a school medical officer is to act as adviser to the local education authority through the *chief education officer* on all matters pertaining to the health and physical welfare of children"; and that the medical officer's duty is to report any defects in sanitation or equipment of school buildings which may be detrimental to the health of the children to

the chief education officer and to none else. The height of presumption is, however, reached in the following declaration: "It is important to establish the principle that the school medical officer's report is a report to the Education Committee, who are consequently at liberty to publish such report in whatever form or with whatever alterations they see fit. . . . The report should, in common with other documents to be placed before the Education Committee, be presented through the chief education officer." In other words, the Local Education Committee is to give a free hand to its education officer to mutilate or rewrite its medical officer's reports. On what grounds, it may well be asked, is this claim to the lay editing of a medical report put forward? Here is the answer: "The school medical officer or the medical officer of health, when acting as such, is not in the position of medical officer of health acting in that capacity, in that his report is not made in accordance with statutory conditions as to publication." That there may be no doubt as to who means to be master, the right is demanded in so many words that all communications from the school medical officer or his assistants shall pass through the chief education officer; that all forms and circulars issued by the former shall be approved by and issued through the latter; and that all reports of the former of whatsoever kind shall be presented to the Local Education Committee through the latter. "In short, the Chief Education Officer must be the chief executive officer of the Education Committee in all matters."

We were aware that minor bureaucrats suffered at times from delusions of grandeur. In this instance the delusions would seem to be collective. Even so, little harm might perhaps be done if these local officials amused themselves by airing their pretensions in strict privacy; but their memorandum, to which we have referred, appears to have been circulated by the County Councils Association to county medical officers, not for comment and criticism, but "for private and personal use." So far as we are aware neither the County Councils Association nor its education committee has expressed an opinion upon the claims advanced by the Association of Directors and Secretaries of Education. It would be of interest to know whether the County Councils Association has yet formed any opinion on the administrative principle involved, and if so, what its nature may be.

The matter thus being common knowledge among those most concerned, the British Medical Association and the Society of Medical Officers of Health have decided that prompt action is needed. The two organizations have agreed to send in a memorandum to the Minister of Health and to ask him to receive a deputation. The opportunity will no doubt be taken to point out the dangers of delay in providing for unification of all agencies which are definitely connected with the health of the nation, and the risks of leaving the school medical service outside the general constructive organization of preventive medicine.

THE SOCIAL STUDY OF A COMMUNITY.

IN the rough and ready study of geography in vogue in schools twenty years ago or even less, the names of the rivers of India and the comparative heights of the mountains of the world were learned by rote and forgotten at leisure. To-day, however, under modern teachers of geography, the schoolboy begins with the study of his immediate surroundings, their physical features, climate, industries, local government, and so proceeds to wider horizons and more general knowledge. In human physiology advances have generally been achieved, first by the intensive study of small details, by the careful watching of one aspect of one part of an organ, and then by

weaving the knowledge thus gained into the fabric of the whole. So in the life of a nation real advance is not made by chaotic political ideas and war-cries, which loom so large one day and are forgotten the next, but by the development of true knowledge, built up little by little, of the things that constitute the foundations of national well-being. With such an object in view a pioneer effort has been made in Wales by a survey of the industrial, social, and educational life of one town during a period of ten years. The study was made in Aberdare, during the decade from 1910 to 1920, by the members of the Aberdare group of the Welsh School of Social Service. A comprehensive paper based on the considerable mass of material collected was read by Miss Dorothy Rees at the annual meeting, in 1921, of the School of Social Service, and an interesting summary of this paper has been published in *The Welsh Outlook* for January, 1922. Aberdare is a coal-mining district, where the population has increased from 1,500 in 1801, when it was still, of course, agricultural, to 54,000 in 1920. Within the decade studied electricity was introduced; it was generated from house refuse, and employed both for lighting and power and for the tramways. Two housing schemes were begun in 1911, and early in the decade Acts and by-laws for notification of births, employment of children, and shop hours were adopted. Land was secured in all the wards for recreation spaces and open-air swimming baths, and public parks were laid out; Aberdare, too, was early in the field in establishing infant welfare and maternity work. In education the town was a pioneer in the organization of physical training and play centres, and modern methods of education have been introduced. The education authority (for good or for evil) was the first in the kingdom to appoint a whole-time school medical officer, and a school clinic was opened in 1911. A prominent feature in the social life of the town has been the provision of workmen's halls, institutes, and free libraries, which knit together practically the whole community. Aberdare has long been renowned as a centre of music lovers, and in the last ten years over a dozen dramatic societies have also been established. The political life of the community has not differed much from other towns in the country, but its tolerance of widely differing political creeds has been noteworthy, and during the war extremist speakers, who were bitterly assailed elsewhere, were allowed in Aberdare to make public their opinions, although 5,650 of its men served in the army and navy. This miniature Domesday Book is not only a definite achievement but an example worthy of wide imitation.

THE MATERNAL MORTALITY PROBLEM IN NEW ZEALAND.

According to statistics published by the United States Department of Labour in May last, New Zealand took the second highest place in regard to mortality from childbirth and the diseases of pregnancy. This publication led the Minister of Health of the dominion to appoint a special committee to investigate the facts and suggest a remedy. The report of the Committee has now been published in the official periodical of the Ministry, the *Journal of Health and Hospitals* (October, 1921), and it is not without its lessons for us in this country, where the persistence of the mortality rate from the same causes is a standing reproach. The Committee produce a graph covering the period from 1872 to 1920, which shows that after certain more or less ordinary fluctuations there has been a sharp rise in the maternal mortality rate in New Zealand from 1913, reaching a maximum of 6.48 per 1,000 live births in 1920. The principal causes of death are stated as: (1) "Puerperal septicæmia; (2) puerperal albuminuria and convulsions; (3) puerperal hæmorrhage; (4) accidents of pregnancy and other accidents of labour." Thirty-six per cent. of the average maternal mortality for the last quinquennium was the result of puerperal infection, and it is to this subject that the Committee have almost exclusively devoted their report. They give as a reason for so doing that

"Deaths from sepsis are largely preventable," but if that is so, deaths from albuminuria and puerperal convulsions are even more so. We should like to have seen this point mentioned, and the life-saving value of a routine examination of the urine of every pregnant woman emphasized more specifically. For the high death rate from infection the Committee blame: (1) "Abnormal virulence of organisms and diminished resistance of individuals, due possibly to conditions during and subsequent to the war." Included in these conditions are housing difficulties and lack of domestic help. There is also evidence of "an abnormally high death rate due to septic conditions following on attempts to procure abortion." (2) With regard to unsuitable surroundings, it is said "private houses are often quite unhealthy places for confinements. Moreover, some private maternity hospitals are not free from conditions which easily lead to septicaemia and allied troubles." (3) The unduly large use of instruments and other operative measures is condemned; medical witnesses, it is said, stated that too often "the use of anaesthetics and instruments was urged upon the practitioner by the patients and their friends." Making all allowance for the difference between the conditions prevailing in New Zealand and those prevailing here, it may be accepted that all three conclusions are more or less applicable to this country, with perhaps the exceptions of any "abnormally" high rate of abortion-mongering, and the urgency of patients and their friends for the employment of instruments. All we would say about the first conclusion is that it is and must remain more or less a matter of opinion. But we are particularly glad to see reference made to the unsuitability of many private houses for confinements, for we hold that this is a big factor in our own problem at home. If we are to reduce our maternal mortality it is not enough to insist upon the proper training of medical students and nurses; we must educate the people to a comprehension of the necessity for the provision of suitable conditions for confinements. There is no gainsaying that every confinement partakes of the essential character of a surgical operation. The placental site is a large wound surface, and in every first confinement at least there are numerous other small breaches of the surface. Yet practitioners are expected to confine women in conditions in which they would naturally hesitate to "operate," and then illusory immunity with which they appear to do so tends inevitably to produce a contempt of the risks. Many a man does—and in some degree is forced by circumstances—put his hand into a uterus under conditions in which he would never dream of putting that same hand into the peritoneal cavity. Again, we are glad to see the reference to private hospitals or nursing homes. The powers of inspecting such institutions, vested in the local authorities under the Midwives Acts in this country, would be kept in greater respect and efficiency by a little exercise. The recommendations of the Committee are very interesting. With the spirit of them we have no quarrel, but they deserve attention also from the fact that they indicate what may be expected under the bureaucratic rule of an active Ministry of Health. "That every case of maternal death shall be forthwith personally investigated by the Medical Officer of Health, who shall report to the Director-General of Health." "That every case of notified puerperal sepsis shall be forthwith personally investigated by the M.O.H. who shall report to the D.G.O.H." "That all maternity hospitals, public and private, make a quarterly return to the department of morbidity rate as well as mortality rate." This is an excellent recommendation, especially in its emphasis of the importance of the morbidity rate; but we should prefer to see a moral compulsion in response to an awakened public opinion rather than a legal compulsion. Recommendation 5 includes compulsory post-graduate study for practising maternity nurses every two or three years—of course at the expense of the State. Recommendation 8 is that "efficiently equipped private midwifery wards for paying patients should be established in connexion with public midwifery institutions or in other suitable places." This is greatly needed in this

country also. In Recommendation 11 the Committee seeks the co-operation of the profession in preventing excessive use of instruments. This is a most vital recommendation. Putting aside for the moment the inestimable value of instruments properly used in the presence of proper indications, there can be no doubt that thousands of labours are every year conducted instrumentally with detrimental results, which would terminate more favourably without such interference. The gynaecological wards of every hospital afford more than ample testimony to this. Lastly, the Committee lays stress on the importance of ante-natal clinics, and in private practice "the serious importance of ante-natal examination." With this we entirely agree. It is indeed but part and parcel of the proper modern conduct of obstetric practice, and while ante-natal clinics are a comparatively recent development, it is a reproach to the profession that adequate ante-natal examination in private practice should require any stressing.

INDUSTRIAL USES OF MICRO-ORGANISMS.

In view of the proposal recently put forward by Mr. Clouston Chapman, F.R.S., for the foundation of an institute for the study of industrial microbiology, it is of interest to note the examples he gave in the Gantor lectures for 1921 of the advantages reaped by industry from the scientific study of bacteria yeasts and moulds. In the ordinary fermentation of sugar by yeast 3 to 4 per cent. of glycerin is formed as one of the by-products. Early in the war the Germans, faced with a fatal shortage of fats, turned attention to the problem of the increased production of glycerin by yeast fermentation of sugar. As the result of carrying out the fermentation in an alkaline medium in the presence of sodium sulphite the direction of the enzyme action was so changed that glycerin was formed to the extent of 35 per cent. Americans in the later stages of the war produced glycerin by fermentation of molasses in the presence of sodium carbonate, and from 20 to 25 per cent. of the sugar taken was converted into glycerin. Another example of a recent modification of an ancient industry is the modern production of sugar from starch through the agency of a mould of the genus *Mucor*. From very early times moulds have been used in the East for the manufacture of wine from rice. The so-called Chinese yeast was analysed by Professor Calmette, who traced the diastatic action to a *Mucor* mould. The organism was obtained in pure culture and has been used extensively in France for the manufacture of alcohol from starch, maize, rice, and potatoes. Since the process was first introduced, twenty years ago, more than six million hectolitres of alcohol have been prepared by this method, which illustrates the fact that by biochemical research and the application of modern scientific methods a crado process of very little utility, and dating almost from time immemorial, has in the short space of twenty years been raised to a position of high technical importance to the whole world. Recently the process has been further simplified by making use of the starch-liquefying enzyme secreted by *B. mesentericus* for the purpose of preparing the grain for the *Mucor*. In this modification, therefore, three agencies are employed: First, a starch-liquefying enzyme secreted by a bacillus; secondly, the diastatic enzyme of the mould; and, finally, the alcoholic fermentation of the sugar by the yeast. As an example of an industry which has not benefited by the advances of modern science the vinegar industry may be mentioned. The manufacture of vinegar was certainly being carried on in this country in the early part of the seventeenth century, and in the reign of Charles II its taxation was provided for in the Revenue Act of 1673. As is well known, vinegar results from the oxidization of alcohol to acetic acid through the agency of micro-organisms, different varieties of vinegar being formed from the different alcoholic beverages oxidized. The apparatus employed is very crude, the alcohol being allowed to trickle over twigs of wood on which are growing the acetifying organisms. Vinegar manufacturers make no attempt to use pure cultures of the acetifying bacteria, and

they rarely know anything of the precise character of the organisms they are using or the most suitable conditions for obtaining the maximum yield of vinegar. The result is that the process is wasteful and often uncertain in its results. Perhaps the most impressive example of the application of bacterial ferments for industrial purposes is exemplified in the "acetone process" developed during the war, when the demand for acetone was so greatly increased. This process consists of the bacterial fermentation of starch by the acetone bacillus under strictly aseptic conditions, and the separation of the two main liquid products, butyl alcohol and acetone, by fractional distillation. An enormous amount of acetone was manufactured in this way both in England and in Canada during the war, but the commercial possibilities of the method in times of peace depends on whether or not a use can be found for the butyl alcohol formed in such large quantities. In discussing the possibilities of the use of lower fungi for food of man Mr. Chapman drew attention to the German discovery in 1916 of an organism which during its growth produced fat and also built up protein from ammonia salts without any form of organic nitrogen. By a special chemical process it was found possible to prepare from it a food extract resembling extract of meat in its chemical and physical properties. Thus was built up in a few hours from glucose, converted sawdust, and ammonium phosphate, through the agency of this microscopic organism, large quantities of edible protein and fat. These few examples of the utilization of micro-organisms for industrial purposes illustrate the importance of close co-operation between science and industry.

DR. THOMAS FOWLER'S SOLUTION.

FAMILIAR as is Fowler's solution, the identity of Dr. Thomas Fowler is not recognized in the *Dictionary of National Biography*; there is, however, an account of him in the late A. C. Wootton's *Chronicles of Pharmacy* (vol. ii, p. 133, 1910), and the *Presse médicale* of Paris of June 4th, 1921 (*Supplement*, p. 803), contained an interesting historical note by Dr. H. Leclerc. The following is the history of Fowler's solution: Towards the end of the eighteenth century a secret patent specific against ague was popular in Berlin, and these "tasteless ague and fever drops" came into vogue in this country, and were occasionally used from 1780 to 1783 at the General Infirmary of the county of Stafford, where Fowler was physician and a Mr. Hughes the apothecary. In October, 1783, Hughes told Fowler that he had found that the active constituent of this secret remedy was arsenic, and that he had made up a solution of arsenic to take its place; this substitute was tested and compared as regards its effects on patients, and some modifications in its composition were made. In 1786 Fowler published a pamphlet of 128 pages, "Medical Reports of the Effects of Arsenic in the Cure of Ague, Remitting Fever, and Period Headaches; together with letters from Dr. Thomas Arnold of Leicester and Dr. Withering, describing their experience of the effects of arsenic in intermittents." This contained a number of cases so treated, and pointed out that previously arsenic had been regarded in the light of a powerful poison only; indeed, writing again in 1788 he found it necessary to combat this prejudice against its medicinal use. Fowler gave full credit to Hughes for his investigations, but, as Leclerc points out, the preparation should perhaps be more justly called Hughes's solution. It is generally recognized that Fowler introduced the modern medicinal use of arsenic, and it is interesting to note that he derived it from a quack remedy. He also wrote *Medical Reports of the Effects of Tobacco in the Cure of Dropsies and Dysurics*, describing the diuretic action of tobacco; this passed into a second edition. Fowler was born in 1736 at York, where from 1760 to 1774 he kept a chemist's shop; he then went to Edinburgh and took his M.D. degree, and settled down to practice in Stafford. In 1793 he was seized with a painful affection, variously diagnosed by his colleagues. Leclerc summarizes the condition as "paroxysms of convulsive asthma with very painful symptoms of angina," and

a year ago there was on sale an autograph letter, written from York on June 3rd, 1795, by Fowler, asking for advice and detailing his symptoms as those of angina, to W. Withering, M.D., F.R.S., of Birmingham, the introducer of digitalis, which Withering endorsed with the diagnosis of spasmodic asthma. After leaving Stafford and trying all sorts of remedies for two years Fowler recovered completely, and in 1796 became physician to the lunatic asylum founded by the Quakers at York, where he died in 1801.

THE PROGRESS OF CREMATION IN ENGLAND.

DURING 1921 the number of cremations carried out at British crematoriums was, curiously enough, 1,922. This figure was 126 more than the total for the previous year, but 109 below that for 1919, the "record" number of cremations in that year being mainly accounted for by the influenza epidemic. The bodies of many notable persons who died last year were cremated, including, amongst medical men, Sir Felix Semou, Sir George Savage, Dr. P. S. Abraham, Mr. H. E. Juler, Dr. A. S. F. Leyton, and Sir Sidney Beanchamp. The hygienic advantages of cremation have been dwelt on so many times in these columns that the arguments in its favour must be familiar to all members of the medical profession. From an economic point of view it has the advantage of preserving land for the use and enjoyment of the living; it provides, moreover, a permanent resting place for the dead, in accordance with the ancient custom of church sepulture. Sir Thomas Browne, in his famous dissertation on urn burial, remarks that "carnall interment or burying was of the elder date. . . . But the practice of Burning was also of great antiquity, and of no slender extent." The early Christians, he says, abhorred this way of obsequies, but the Jewish nation, though they entertained the old way of inhumation, at sometimes admitted this practice. Such phrases as "cadaverous and corruptive burials" seem to show his own reference for "urnall interments and burnt Reliques." At cremation, although it is now being adopted in nearly every civilized country, makes slow progress in superseding with burial as the accepted method of disposal of the dead. Of the fourteen crematoriums in England and Scotland—all placed in large centres of population—it appears that not more than six are at present paying their way. The reason for this is that they are not made use of often enough to cover ordinary working expenses in respect of establishment and maintenance, rates and taxes. The Cremation Society of England finds that, provided it has the support of only some 10 per cent. of the population of any large centre, a crematorium becomes a paying concern; furthermore, unlike a cemetery, it never becomes filled up and useless or a danger to health. Cremation would no doubt progress more rapidly, at least among educated people, if those who favour it recorded their wishes during lifetime and thus identified themselves with the movement. In recent years the Cremation Society of England, whose offices are at 52, New Cavendish Street, London, W.1, has instituted a scheme of registration whereby those in sympathy may record their wish. There is no charge for this service, and no liability attaches to those signing or to their executors, but the society endeavours to give effect to the desire so expressed.

SMALL-POX AND VACCINATION.

It is stated that there are in England and Wales at the present time about 15,000,000 persons unprotected against small-pox, including great multitudes of unvaccinated children. While it is unlikely that this country, with its admirable public health service, will ever have such a visitation of small-pox as less civilized countries have had in former times, yet the fact remains that small-pox does prefer unvaccinated to vaccinated children. A leaflet which has been issued by the Research Defence Society points out that there is a part of the Gloucester cemetery where 279 unvaccinated children under ten years of age are buried, who died of small-pox in the Gloucester epidemic of 1895-96;

with them is only one child out of more than 8,000 who were vaccinated before or during the epidemic. During the small-pox epidemic in London in 1901-2, of the deaths from small-pox in children under ten years of age, 442 were among the unvaccinated and only 2 among the vaccinated; while similarly in Glasgow in 1920, during the epidemic of that year, 36 unvaccinated children died and none of the vaccinated. In the epidemic at Ossett, in 1903, in a school of 169 children living under similar conditions there were 37 cases of small-pox among the 77 unvaccinated children, 5 among the 78 vaccinated, and none among the 14 revaccinated. Vaccination is not our only defence against the spread of small-pox: the disease is fought also by sanitary measures, but the great abatement of small-pox was certainly already achieved by 1812, before the rise of modern sanitary science. The Public Health Act, for instance, did not become law until 1875. The case of a well known public man in London having recently contracted small-pox through exposure to infection in Russia has focused attention again upon this disease, especially as in this case the disease was considered at first to be a somewhat severe form of chicken-pox, which, of course, it resembles closely in its early stages. The London County Council, it will be remembered, has made arrangements, with reference to small-pox, by which medical practitioners in its area can have the benefit of the opinion of a specialist at any time on application to the public health department of the County Council, at 2, Savoy Hill, W.C.2 (telephone: Gerrard, 3641).

POST-GRADUATE COURSES IN LONDON.

THE Fellowship of Medicine and Post-Graduate Association has arranged for a special course in surgery on lines similar to those of the course in medicine now in progress. Much will, no doubt, be learnt from these experiments. It may be, as some critics say, that the first quarter of the year is not the best season, and six weeks may be too long; but the needs and opportunities of post-graduates vary, and we trust that, whatever the result, the Fellowship of Medicine and Post-Graduate Association will be encouraged to repeat the courses at another season and to institute others of shorter duration. The course in surgery will begin on February 20th and conclude on April 1st. The hospitals taking part are the Cancer Hospital, the Chelsea Hospital for Women, the Royal Free Hospital, the Hampstead General Hospital, the Royal Northern Hospital, the Queen's Hospital for Children, the Royal National Orthopaedic Hospital, the National Hospital for the Paralyzed and Epileptic, St. Mark's Hospital for Diseases of the Rectum, St. Peter's Hospital for Stone and other Urinary Diseases, and the North-East London Post-Graduate College. There will be a morning and afternoon session on each day of the course, and the appointments will be so arranged as to involve a minimum of travelling. The arrangements are nearly complete, and a syllabus will shortly be available on application to the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

KEW GARDENS.

SIR DAVID PRIN is about to retire, under the age rule, from the Directorship of the Royal Botanic Gardens, Kew, which he has held since 1905. *Nature* announces that he will be succeeded by Dr. A. W. Hill, who has been assistant director since 1907. Sir David Prain, who graduated M.B., C.M. at Aberdeen in 1883, entered the Indian Medical Service in 1884, and three years later became curator of the Calcutta Herbarium, a post he retained until 1898, when he was appointed director of the Botanical Survey of India and superintendent of the Royal Botanic Gardens, Calcutta. This post he held until his appointment to Kew. The Royal Botanic Gardens, Kew, are known to all Londoners as one of the most delightful resorts within easy reach of the centre of the metropolis; but they are far more than that: they are the centre for research in scientific and economic botany of the British Empire, and under Sir David Prain's direction

have maintained the eminent position achieved for them by his distinguished predecessors. He has received many distinctions. He is treasurer of the Royal Society, has been President of the Linnean Society, and is President of the Association of Economic Biologists. During the war he rendered important services to the War Office and other Government departments. His successor, Dr. Hill, is F.R.S., and before his appointment to Kew was lecturer in botany in the University of Cambridge, of which he is a graduate.

INFLUENZA.

In the week ending January 14th the number of deaths from influenza in the 105 great towns of England and Wales exceeded 1,000; in London 551 deaths were recorded, an excess of 197 over the figure of the previous week. It will be noticed that the rate of increase is slackening considerably, and we shall not be surprised if, so far as London is concerned, the last week proves to have been the worst of the present recrudescence. In Nottinghamshire and the West Riding, the earliest areas affected, the crisis is past. Clinically there is no doubt that the disease is generally of a mild type. Pulmonary complications have been less common and less severe. The "heliotrope" pneumonia of 1918 has been excessively rare, and, in the few cases reported, recovery has taken place, which was very unusual in 1918; as the lay press are tempted to thrill their readers with reports of "deadly blue" pneumonia, it is worth bearing the point in mind. So far as our information goes there is a great deal of influenza in Germany, but it has not been reported from France, and the North American continent appears at present to be free.

England and Wales.

WELSH NATIONAL SCHOOL OF MEDICINE.

A public meeting to support the appeal of the Prime Minister for £100,000 to provide additional endowment and equipment for the Welsh National School of Medicine will be held at the City Hall, Cardiff, on Wednesday next, January 25th, at 3.15 p.m. The speakers will include Professor Sir Charles Sherrington, President of the Royal Society, the Right Hon. J. Herbert Lewis, M.P. for the University of Wales, Sir George Newman, K.C.B., M.D., and Lord Kenyon, Pro-Chancellor of the University of Wales. The Lord Mayor of Cardiff will be in the chair. It is urged that the sum asked for should be raised before August next, so that the Welsh National School of Medicine may qualify for the annual Treasury grant of £5,000. It is estimated that within a year or two the yearly expenditure of the school will reach £25,000. Money is also required for equipment in the shape of laboratories and apparatus, and for an endowment fund to provide the full complement of professors, lecturers, and trained staff. The organizing secretary of the fund is Mr. Gwilym Hughes, Welsh National School of Medicine, Newport Road, Cardiff.

HOSPITAL ACCOUNTS AND PATIENTS' PAYMENTS.

In view of recent developments in connexion with the income derived from receipts for services to patients, certain modifications have been made in the revised uniform system of hospital accounts by the King Edward's Hospital Fund, the Metropolitan Hospital Sunday Fund, and the Hospital Saturday Fund, which will affect all hospitals in the London area receiving grants from these funds. Instead of the former heading which dealt with the income from patients' payments and under the National Insurance Act, five sub-headings are now to be used, which will distinguish the amount of the receipts from in-patients, out-patients, public authorities, approved societies, and other sources. The definition of patients' payments will apply to all receipts on account of services to patients, whether the receipts are from patients themselves, or from their friends, charitable agencies, public authorities, or other sources on their behalf. It is particularly emphasized that only exceptional voluntary payments quite outside the rules of a hospital as to patients' payments should be included under the heading of donations, and all receipts which result from applications made to

patients to contribute towards the cost of services rendered should be included under the heading of receipts for services to patients.

A HOSPITALS WELFARE SOCIETY.

The Lewisham, Deptford, and Greenwich Hospitals Welfare Society is, we are informed, raising approximately £100 a week for local hospitals, by means of the "Wilfred Allen scheme" for collecting small amounts from the householders of the district. The scheme is worked by more than 1,700 voluntary workers, and in nine months of last year the society was able to allocate £3,600 to the five local hospitals and the Sydenham Infant Welfare Centre. A large proportion of this sum was taken in pennies from door to door; it is expected that in the present year the amount will be much increased. The secretary, Mr. Edgar F. Brooks (75, High Street, Lewisham, S.E. 13), states that the society welcomes inquiries from other hospitals or areas, and will be pleased to explain matters fully and to help in the organization of any district. The society holds that the voluntary principle "is of paramount importance for the really effective working of the hospitals, and that by an organized effort that principle can not only be maintained but greatly extended." Its desire is to present the scheme as a free gift to the cause of humanity, to maintain the hospitals on the basis of voluntary contributions. It has, we are informed, been adopted with much success in Barking.

METROPOLITAN ASYLUMS BOARD WAR MEMORIAL.

At the meeting of the Metropolitan Asylums Board on January 14th the memorial tablet erected by the Board in memory of officers of the Board who fell in the war, was unveiled by the chairman (Canon Sprankling). The memorial, which was designed by Mr. J. N. Comper, consists of a panel upon which the dedicatory inscription and 132 names of those who gave their lives are cut. The panel is enclosed in a projecting frame, and surmounted by a cornice supporting the Board's arms, the whole being carved in Nailsorth stone and decorated in gold and colour. The chairman, in unveiling the memorial, stated that 1,649 of the staff joined the forces, and 104 decorations and honours were gained. The Board is at present employing over 7 per cent. of disabled men amongst its male staff.

Scotland.

A GLASGOW UNIVERSITY APPEAL.

An appeal is being made by Glasgow University for funds to extend the Students' Union, the Women Students' Union, the hostel accommodation for students, the Athletic Club pavilion, and to provide an endowment fund for the Athletic Club. Handsomely endowed and equipped for instruction in arts and sciences, in these other respects (which are to-day recognized as equally important in the training of the student) Glasgow takes a humble place in comparison with other universities, and especially with the ancient foundations of England. There was a time in the early history of Glasgow when its college was residential, but the time came when Scotland in general came to pin its faith upon class work and examinations, leaving—if they were considered at all—culture and character to nature rather than nurture. The present Students' Union of Glasgow was presented by Dr. John McIntyre, in 1899, to be "a centre to which the various university societies may be affiliated." At Glasgow the Union is the very heart of the university, but, although the original building has been extended twice, it is now capable of accommodating only a membership of 500. But there are 3,300 men students at the university, of whom 1,200 are members of the Union. There are fifty student societies at present at Glasgow, but their meetings are greatly hindered through the absence of accommodation in the building designed for them. The crowding conditions that affect the men apply equally to the women students of Queen Margaret College, who have urgent need of a new union also. In October, 1920, no fewer than 1,075 women students matriculated, and for them there is available in their union a dining-room able to seat only thirty at a time, while the largest room in the building holds but fifty people. Students of Glasgow have to seek lodgings in the city, and owing to the present shortage of houses the difficulties are many. There is thus a real and urgent call for hostels for about 600 students, men and women, for as things are at present 676 men and 237 women students at the university have

to live beyond twelve miles from the city. The present hostel accommodation provides for fifty women only, and for some forty men. The Athletic Club equally needs assistance; the only pavilion is a temporary erection where the numerous members of the various sections of the Athletic Club have to change in two small rooms, while the women students are even less luxuriously accommodated in a hut. In order to provide a staff sufficient to keep and work the enlarged athletic ground, an endowment is necessary to meet the permanent charges, for there is no resident body of past players to support the club by their subscriptions as honorary members, as is the case in ordinary athletic clubs. The University of Glasgow therefore appeals to all her members and friends to help generously in her efforts to meet these real needs, of which the experience of the past few years has made her more conscious than ever before.

INFLUENZA IN SCOTLAND.

In Edinburgh there have been so far comparatively few cases of influenza, which have proved of a mild type, but in Glasgow the number of cases has been steadily increasing, and while the number of deaths has been small the prevalence of the disease has given rise to considerable apprehension. According to the *Glasgow Herald* nearly 200 members of the police force were off duty on January 12th, the majority of whom were suffering from influenza, while among tramway men, who from the nature of their employment are specially liable to attack, there were no fewer than 280 cases. Among school children the disease is likewise spreading, and the number of absences from school is also increased by an outbreak of measles which has occurred. In Kirkcaldy it has been estimated that fully 3,000 people are off work suffering from influenza, and in some cases as many as 50 per cent. of the employees of business houses are ill. The suggestion has been made in Edinburgh that, owing to the fact that all trained nurses are fully engaged, an emergency staff of those who have had nursing experience should be formed, whose services might prove very useful in case the influenza epidemic reaches Edinburgh.

GLASGOW MEDICAL LUNCH CLUB.

At the weekly meeting of this club on January 12th, in Ferguson and Forrester's, Buchanan Street, Dr. Frank W. Martin presided, and Dr. James A. Adams was present as the guest of the club. After lunch Dr. Adams, who represents the Royal Faculty of Physicians and Surgeons of Glasgow on the General Medical Council, gave an address in which he referred more particularly to the efforts being made, or about to be made, to raise the standard of medical education in general. He discussed the proposal to raise the standard for the D.P.H., proposals which if accepted would render the diploma very difficult to obtain. A higher qualification of this kind was in his opinion suitable for those who wished to specialize in public health, and should be additional to, and not replace, the present diploma. Dr. Adams finally made a strong appeal for a larger membership of the Royal Faculty in Glasgow, so that its present influence in medical matters, local and general, might be strengthened.

BELLAHONSTON HOSPITAL.

At the monthly meeting of the Fellows of the Royal Faculty of Physicians and Surgeons of Glasgow, held on January 9th, 1922, the following resolution was passed respecting the administration of Bellahouston Hospital:

After careful consideration the Faculty are of opinion that the report of the Committee of Inquiry into the management of Bellahouston Hospital affords a complete vindication and exoneration of the administration of the hospital and of the medical and surgical staffs.

Ireland.

MEDICAL ADVANCE AND DEVELOPMENT IN BELFAST.

(From our Belfast Correspondent.)

THE large benefactions of the late Mr. Henry Musgrave of Belfast have raised considerable debate amongst those interested in the public institutions concerned; some of these bodies will no doubt be glad of the immediate relief in this time of financial difficulty. With regard to the Royal Victoria Hospital, it is considered an opportunity for some

large developments. With great foresight and care the financial authorities of the board of management have kept the income at a high level; the workmen's contributions are liberal and much increased, and in the hospital itself economy has been pressed in all departments, provided that efficiency was not sacrificed. Much praise is due to Colonel Deane, ex-superintendent, and to his indefatigable successor Colonel Forrest. The result is that towards the end of the financial year there is a legitimate hope that if there be a deficit it will be but small, and that in this respect the hospital will compare most favourably with similar institutions. Consequently there is place for further enterprise. The foundation of a "clinic" on the lines of those started in some of the leading London hospitals, the building of a large and suitable nurses' home, the enlargement of the hospital by the addition of one or two units, and, lastly, the erection in connexion with the main hospital of a well equipped "pay" or "private" hospital for the middle classes. At present we have several excellent and well managed private hospitals, run by former nursing sisters; the charges are not exorbitant for the well-to-do and rich, but for the poorer middle class the minimum charge which it is found necessary to make to ensure a profit is prohibitive; this large and deserving portion of the community are not catered for; they can afford a moderate weekly sum towards their maintenance in hospital and a moderate fee for professional attendance, but they cannot afford a weekly sum that pays the proprietor of a private nursing home nor a fee that pays a medical attendant and a consultant or operator, and they refuse charity. One large institution could be run on more economical lines than several smaller independent ones, and the conditions would be more uniform. This project finds favour with many of the profession. The new plans of the Leeds Medical School (vide *BRITISH MEDICAL JOURNAL* of January 7th) have also received very favourable comment.

With regard to the university there is also much interest and debate; no doubt the arts, science and other faculties, will press their claims. In the faculty of medicine, which is by far the largest in the university, advances have in the last few years been made in the departments of anatomy, physiology, and pathology; the lectureship in public health has recently been raised to a professorship; a department of dentistry, with powers to confer a diploma, is now in full swing; and midwifery and gynaecology have now separate professors; in medicine and surgery no change has been effected for years; a lectureship in pharmacology is felt to have the first claim; but although no doubt evidence can be brought that the subjects for the half and third examinations are widening and require support for new efforts, yet the final subjects will have either to assert their importance and their far-reaching influence in the light of modern science, or else sink into a merely technical training. We have six teachers in physiology, and but two—both part-time—in medicine, including acute infectious diseases, constitutional diseases, heart, lung, urinary, digestive, and blood diseases, neurology, psychiatry, dermatology, tubercle, and much of syphilis, etc. Surely this is stultifying the study of these subjects. Medical education and study may roughly be divided into three degrees or grades—that of the general practitioner, that of the specialist, and that of the research worker; any one of them requires the greatest brains we can give; it is a question of direction of study, not of ability. In the final subjects the standard of the first in Belfast, as in most medical schools in Great Britain, is high, and leaves nothing to be desired, but practically no effort has been made by the university to provide post-graduate work in the final subjects, in specialist's training, and, most important of all, in research work. The Royal Commission on University Education in London in 1913 found the same fault—the schools did not encourage research; the clinical teacher should be himself engaged in the discovery of fresh truths and should be at the growing point of knowledge. This finding was endorsed by the University Grants Committee in 1921 (page 11 of their report). In the report of the Development Committee of the Queen's University of Belfast (1919) no recommendation, except a slight increase in salaries, was made with regard to these final subjects. A department of medical research or experimental medicine was recommended, but in a half-hearted manner, without detail and with an altogether inadequate grant. A strong hope is now entertained that with the aid of this large benefaction there will be a beginning in endowing scientific research in the final subjects and an earnest effort

made to enable clinical teachers to be at the growing point of knowledge. Confining attention for the moment to the domain of medicine, it may be said that lectureships with opportunities of research in neurology, psychiatry, metabolism, cardiology, dermatology, experimental psychology, tuberculosis, applied bacteriology and immunology, haematology, and syphilology, would prove generally valuable additions to the strength of the medical faculty, would promote research amongst those who are faced by the problems of the bedside, and would form a school for post-graduate instruction, and so be a valuable asset to the profession in Ulster. Great advances have no doubt been made by physiologists, anatomists, and pathologists, but the most valuable discoveries have been due to the work of those who had to face the realities of disease and daily receive the stimulus of direct contact with patients. Lister, and the pioneers of abdominal and brain surgery, and in the study of endocrinology, all received this double training and experience.

The senate of the university has recognized the importance of the medical school rising to the latest standards, and lately appointed a special committee to consider the enlargement and development of the medical school.

DEATH OF A BELFAST PHILANTHROPIST.

The death of Mr. Henry Musgrave, D.L., O.B.E., in the early days of this year removed a well known and much respected and beloved philanthropist and public benefactor; he was the last of a large family of brothers, and the Musgrave Chair of Pathology in the Queen's University of Belfast, the Musgrave Laboratories, and the Henry Musgrave Chair of the Russian Language and Literature—lately by consent of the founder devoted to Spanish—are but a few of the standing evidences of the interest of the family in education. His will continues his benefactions; £47,000 is left to the Queen's University, of which £20,000 is to be devoted to research scholarships, £20,000 to general purposes, and £7,000 to a readership in physics; £50,000 is left to the Royal Victoria Hospital, Belfast, and this institution is also residuary legatee; £20,000 is bequeathed to erection of four national schools; £10,000 to each of the two children's hospitals; £1,000 to the Samaritan Hospital; £5,000 to the Society for providing Nurses for the Sick Poor; £2,000 to the County Infirmary, Lisburn—his native town; £2,000 to the Royal Medical Benevolent Fund Society of Ireland; £2,000 to the Belfast Charitable Institution; £1,000 to the Belfast Maternity Hospital; £1,000 to the Stewart Institution for Imbecile Children and Hospital for Mental Diseases, Dublin; £1,000 to the Ulster Hospital for Diseases of the Skin; £1,000 to the Benn Eye, Ear, and Throat Hospital; £1,000 to the Cripples' Institute, Belfast; and many other sums to various Presbyterian institutions, of which denomination he was a devoted member. His pictures he bequeathed to the Belfast Municipal Art Gallery, his library to the University, and his residence, Drumglass House, and grounds as a public park. He left also several private legacies.

India.

INDIGENOUS MEDICINE IN INDIA.

THE Ayurvedic and Unani systems of medicine are still widely popular in the United Provinces, and the policy of the Government is to help in the extension to the poor of all kinds of medical relief, including the indigenous systems of medicine. For the encouragement of the latter the United Provinces Government has included a sum of Rs.25,000 in the current year's budget. The step was in part experimental, and the Government has not yet come to a final decision as to the best methods of affording financial assistance. It is, however, inclined to the opinion that the following methods are likely to be the most fruitful: (1) To give grants to local bodies to establish travelling or stationary Ayurvedic or Unani dispensaries. (2) To give grants to existing Ayurvedic or Unani dispensaries provided that they are controlled by influential managing committees. (3) To give grants to existing institutions for the training of vaidas and hakimis subject to the same proviso. The question of the management of Ayurvedic and Unani dispensaries maintained by local bodies is not free from difficulty. The ordinary medical staff of the district will not be available for the purpose, and the Government is of opinion that supervision will be

best exercised through health committees of the local bodies concerned. No definite rule is laid down with regard to grants to private institutions, but before a grant is made the Government will require proof that the managing committee is influential and that the control exercised is adequate. The grants to local bodies have been allotted in most cases on the principle of giving three-fourths of the amount required for the year for the maintenance of the dispensaries which the local bodies propose to establish, but grants will not actually be made unless the local bodies agree to provide one-fourth of the actual expense. In future years the Government will insist on local bodies bearing a more substantial portion of the burden. In addition to Rs.25,000 distributed to various centres a sum of Rs.50,000, non-recurring, has also been sanctioned for an Ayurvedic college established at Haridwar.

THE HOUSING QUESTION IN INDIA.

The acuteness of the housing question in Great Britain and other lately belligerent countries has been reflected in India. Indeed, in that country the problem carries a peculiar complication of its own in the failure of the cantonment bungalow to respond to modern requirements of comfort, in contrast to the increasingly high standard obtaining at home. In the ordinary cantonment bungalow to-day exactly the same amenities are provided as were available to the officer and his wife in the Mutiny days, with the exception of those bungalows in which electric light and fans have been established. White-washed walls, thatched or mud roofs and ceilings intersected by rough-hewn wooden beams, are as much in evidence in 1922 as in 1857. The rise in the prices of materials and labour has made the landlord more reluctant than ever to pay much attention to repairs, and the continual change of tenancy, owing to the exigencies of war conditions, has added to that reluctance for obvious reasons. The lack of accommodation, moreover, has had the effect of raising rents and in causing officers to search for dwelling places far from the scene of their work. The Government has, however, now taken the matter up, and is proposing to acquire certain mess houses and to build, either in the mess compound or in the immediate neighbourhood, quarters for bachelors, and thus to release houses for the use of married officers and their families. To meet the difficulties of the situation a further innovation is being introduced in the shape of the erection of hostels for married families. The first of these hostels is shortly being opened at Lahore, where this problem has long been especially acute, and others will follow in stations where the circumstances warrant their erection.

INDIAN RED CROSS SOCIETY.

The Indian Red Cross Society was constituted in 1920 to carry out the administration of the funds and property of the Joint War Committee of the Indian Branch of the British Red Cross Society and the Order of St. John of Jerusalem. The foundation of the society was largely due to the efforts of Sir Claude H. Hill, who retired from the Indian Civil Service in 1920 and is now Secretary-General of the League of Red Cross Societies at Geneva. The objects of the Indian society include not only the administration of gifts received from the public for medical and other aid to the sick and wounded of the Forces, either on the active list or demobilized, but also for the care of sufferers from tuberculosis, for child welfare, for comforts for hospitals and other institutions, assistance to the different branches of nursing and welfare work in India, and home service ambulance work. Dr. D. H. Mehta, of Baroda, has published, under the title of *World's Welfare*, an interesting account of the foundation and development of the Indian Red Cross Society, its relations with the International League of Red Cross Societies, and its programme of work in India for the future.

PLAGUE IN INDIA.

During the later part of 1921 the number of cases of plague in India rose gradually from 365 notified for the week ending July 23rd, to 1,403 notified during the week ending October 8th. From that date the number of cases slowly declined, and for the week ending November 19th, the last week for which figures are available, the number notified was 1,199. The mortality seems to have been high; for the week ending October 8th, for instance, of the 1,403 cases reported, 1,152 were fatal, while in the week ending November 19th, of the 1,199 cases reported, 869 were fatal.

Correspondence.

TREATMENT OF CARCINOMA OF THE CERVIX.

SIR,—In 1905, at the Leicester meeting of the British Medical Association, Wertheim brought to the notice of British gynaecological surgeons the operation of abdominal panhysterectomy for carcinoma of the cervix devised by himself and known by his name. I performed my first operation in the late summer of that year, and have performed it as the routine operation ever since. I very soon realized its difficulties, and that only constant practice and experience would enable me to perform it with adequate dexterity, and would lead to the measure of success the operation itself merited. I think this will be the admission of every surgeon who has begun at the beginning and perseveringly followed the operation through. For instance, in point of time alone my first attempts used to last round about two hours; my average time now is between fifty and sixty minutes; nor do I think that in any but quite exceptional cases the operation can be completed in much less time than this.

Again, in details of technique and little things that matter in a difficult operation experience only has preceded improvement. In 1913 I read a paper before the Gynaecological Section of the Royal Society of Medicine advocating a certain technique and a modification of the operation involving crushing clamps and the canterly in the treatment of the parametrium and vagina in place of cutting and ligaturing. This is the operation I have invariably practised during the past ten years. In the *British Journal of Surgery* (vol. ii, No. 5, 1914) I published an account of the operation and of the technique I employ, and with it particulars of the first 18 cases operated on by this method (from July, 1912, to April, 1914), with 17 recoveries and one death, a mortality of 5.5 per cent., practically that of vaginal hysterectomy. Of course this is too small a number on which to estimate the primary mortality, but it is sufficient to establish the reliability and efficiency of the operation. Then came the war and with it a blank as far as reliable records are concerned. Throughout this time I was operating by this method, but I was only able to attend the hospital and do some of the major operations, and records and notes of cases were either not kept at all or are valueless for statistical purposes. Since midsummer, 1919, I have records which I hope to collect and publish later.

As regards operability rate, I regret I have no figures. This must vary with the judgement of different surgeons. My practice is the following: Every case is examined under an anaesthetic some days before operation to determine as far as possible whether the case is operable or not, to remove a portion for microscopical examination, and to curette away all the soft growth and apply the actual canterly to the base of the ulcer. If the case is manifestly inoperable, nothing further is done from a radical point of view. In any case where the least doubt exists the patient is prepared for operation, the abdomen is opened, and the decision is taken then. Any case which offers the smallest probability of satisfactory removal is tackled, and for this reason, that here, as elsewhere, in dealing with malignant disease, surprisingly good results may follow in apparently hopeless cases. That is my argument against picking and choosing in dealing with malignant disease anywhere. The result is inevitably fatal if the case is refused operation, whereas sometimes a prolonged freedom from recurrence is obtained in a case in which every circumstance appeared to forbid it. Of course, the surgeon who operates with one eye on statistics will obtain a better average in a series of cases by picking and choosing.

The two real dangers of the operation are shock and sepsis. I am glad to be able to state that by the technique and method I employ I have abolished the latter. I no longer see sepsis, though it occurred with considerable frequency in my earliest attempts. Briefly, the method is to curette away all the soft growth just before the operation and apply the actual canterly to the base of the ulcer; to dry out the vagina thoroughly and paint it with iodine in spirit, and to plug the canterized cavity of the ulcer and the vagina with sterilized gauze, which is left in position till just before the vagina is cut across; to crush the parametrium at the pelvic wall and the vagina with powerful crushing clamps and cauterize them,

and to leave the vagina open. Only four ligatures are used in the operation to secure the ovarian and uterine arteries.—I am, etc.,

Portsmouth, Jan. 16th. CHARLES P. CHILDE, B.A., F.R.C.S.

SIR,—It is surely incumbent on those who essay to criticize the results of Wertheim's operation to realize that they should do so with some sense of accuracy and responsibility.

Both Dr. Spencer and Mr. McCann state that the mortality of the operation is about 20 per cent. Do they refer to the mortality of the operation as practised by experts seven or more years ago, or to the mortality of the operation as practised by experts to-day? If they refer to the past, then their letters have no point, for it is with the present in this matter that surgery is concerned; while, if they refer to the present, then they have not taken the trouble, before embarking on criticism, to read Victor Bonney's and Fletcher Shaw's papers with that care which ordinary courtesy, let alone a regard for scientific accuracy, demands.

Mr. Victor Bonney in his paper gives the mortality for the first 100 Wertheim's operations that he performed as 20 per cent., the last operation of the series being performed in July, 1915—that is, six and a half years ago. Since then Mr. Bonney and I have performed the operation a large number of times with an ever-diminishing mortality. Mr. Bonney in his paper has set out this diminishment by means of a table so large and conspicuous that it passes my understanding how Dr. Spencer and Mr. McCann can have failed to see it. In that table it is shown that the operative mortality for the last 200 operations jointly performed by me and my colleague was 13.5 per cent., for the last 100 jointly performed 9 per cent., and for the last 50 jointly performed 6 per cent.

Mr. Fletcher Shaw, whilst giving his mortality as 19.1 per cent. for his series of 89 operations, expressly states that if he deducts the cases performed in 1911-12 the percentage mortality for the remainder is much less than this; but he might as well have spared himself the trouble of making the statement for all the notice that Dr. Spencer and Mr. McCann take of it. The humorous thing is that Mr. McCann in his letter first states that the mortality is 20 per cent. and then two paragraphs further down informs us that he has operated on 100 cases with 6 deaths. Why make the first statement when the second flatly contradicts it? He objects to an "operability rate," but without it no just comparison between different surgeons' results for the purpose of estimating the value of the operation is possible. The point that really matters is what is the total number of patients saved per 100 first applying for relief? His suggestion that a surgeon might perform rash and hazardous operations to maintain a high "operability rate" seems to me unworthy.

I again reiterate what I said in my first letter—that figures concerning the operation are of no value unless founded on a long series of cases dealt with on a basis of three, five, or seven years' freedom from recurrence, and Dr. Spencer and Mr. McCann would be best employed producing such figures of their own.—I am, etc.,

London, W., Jan. 16th.

COMYNS BERKELEY.

SIR,—Mr. Bonney's interesting paper upon the results of the radical operation for carcinoma of the cervix (*BRITISH MEDICAL JOURNAL*, December 31st, 1921, p. 1103) is extremely valuable, but, I venture to think, somewhat incomplete in its statistics; answers to the following questions would add materially to its interest.

Out of his 160 cases 100 were submitted to radical operation. How many of the other 60 were found to be "absolutely untouchable" by operation? What was the mortality? How long did the patient live after the operation? How much of that time was spent in hospital, convalescent home, and infirmary? And to what extent was the patient incapacitated from carrying on her daily work as a result of the operation?

Of the 100 cases, how many would come under the category of "riding for a fall"? What was the mortality, the incidence of recurrence, the interval between the operation and such recurrence, and the length of life from the date of operation?

Mr. Bonney's concluding remarks upon the use of radium in carcinoma are not so valuable as the rest of his paper, for the comparison of radium with a red-hot poker is hardly worthy of him. It is not necessary to remind Mr. Bonney that, for the moment, the discussion ranges round the com-

parative merits of operation or radium in the treatment of inoperable cancer of the cervix; that the universal opinion abroad is in favour of radium; and that up to now what evidence we have from English surgeons supports that view. —I am, etc.,

London, W., Jan. 16th.

SIDNEY FORSPIKE.

THE IRRIGATION TREATMENT OF GONORRHOEA.

SIR.—Mr. Howard English's case of acute arthritis following the irrigation treatment of acute gonorrhoea, and also Mr. Russ's reference to this method of treatment during the war, as reported in the *BRITISH MEDICAL JOURNAL* for January 14th, once more raise the question of the present position of the treatment of gonorrhoea by the irrigation method. As one who was responsible for introducing the method into St. Peter's Hospital many years ago, and so to some extent into this country, perhaps I may be allowed to make a few remarks thereon.

Like almost any form of treatment of an acute infection in such a delicate and vulnerable situation as the male urethra the details connected with its application are of paramount importance. One would like to have had more details of Mr. English's case, but apparently only the anterior urethra was affected and treated as the discharge was only forty-eight hours old. Coincidences are too frequent in the treatment of disease for the report of one case to be of any value. During the war I never ceased warning my friends who happened to be in the R.A.M.C. that the primitive and indiscriminate way in which the irrigation treatment was carried out would certainly bring a valuable form of treatment into disrepute. The outstanding offence was the irrigation into the bladder in a case of acute posterior urethral infection, often with the man in the upright position and without a local anaesthetic. How could a man be saved from a prostatitis, or an epididymitis under such circumstances? I can safely say that not for twenty years have I irrigated at all into the bladder in a case of acute recent posterior urethritis. The acuteness of the attack must be allowed to subside thoroughly before commencing vesical irrigations, and then they should only be done under a local anaesthetic with the patient lying down and with a low head pressure of fluid. Between such a condition and a very mild inflammation when vesical irrigations may be undertaken at once many grades are met with, and this is where experience is of so much value in treatment. When in doubt it is better to trust to medical treatment for perhaps a few weeks before beginning irrigations in a case of posterior urethritis, especially in a first attack.

In quite a different category are anterior urethral infections where the disease has not spread to the posterior portion. But even here a highly acute condition should receive medical treatment for a while before commencing local treatment. In all moderate and mild cases irrigations of weak permanganate, 1 in 8,000, should be undertaken at once and a strenuous effort made to prevent the spread of the disease. Success will attend the treatment in a large proportion of the cases. Should the disease spread to the posterior urethra, and it is recognized very early, vesical irrigations may be undertaken, but they should be at once discontinued if no improvement takes place. My treatment here varies from the French school who irrigate into the bladder in every case of even purely anterior infection. In my practice it is therefore necessary to submit every patient at every visit to the diagnostic test of an anterior wash-out with 2 or 3 pints of a warm solution of mercury oxycyanide 1 in 6,000, or with boric lotion. I should feel quite at sea in the treatment of urethral infections unless this was done on every occasion. The test requires great care and some experience if you want to make quite sure that none of the fluid is going to be forced through the membranous urethra, carrying perhaps some discharge with it and so spoil the urine for diagnostic purposes. A bright urine free from flakes excludes posterior urethritis. A little mucus, or the early separation of a mucous cloud, is suspicious of a commencing posterior infection. Then is the time to try vesical irrigations. It is not possible in a short note like this to make any useful contribution to such a complex subject as the treatment of gonorrhoea, but I hope that the foregoing remarks will help to put the irrigation treatment in its place as a valuable friend which may be easily abused.—I am, etc.,

London, W., Jan. 14th.

W. WYNDHAM POWELL, F.R.C.S.

PROBLEMS INVOLVED IN THE CONGRESS OF THE SEXES.

SIR.—All gynaecologists will welcome the interest in the physiology of their subject by so distinguished anatomist as Professor Arthur Thomson.

It has always been a grievance that most anatomists ignored the anatomy of the female genitalia in their text and textbooks—notable exceptions being Sir Arthur and Professor Wood Jones—and that physiologists have the same in regard to the sex-functions. I do not, however, how far our special science has suffered thereby we have ourselves now worked out many of the problems apparently without the knowledge of the writers of anatomical and physiological textbooks. I hope, therefore, that some general physiologist replies with an address on gynaecological anatomy, it will be more convincing than Professor Thomson, even though well lubricated with nocturnal.

Professor Thomson, in dissenting the endometrial glands makes the following statement: "When we come to in what the functions of these glands may be, we are plunged once into the realms of uncertainty. The generally accepted views are far from satisfying." Then he proceeds to discuss one or two long-forgotten ideas. Nowhere does he give indication of having studied modern work, although he is grieved that Marshall and Young have failed to satisfy curiosity.

In regard to these glands, Professor Thomson was know, "What, then, is their function? Are they secretory absorbent? In truth the views on the subject are very variable (mine). Whose views? I do not think that gynaecologist has any doubt on the matter, nor do I see any physiologist would have much difficulty in deciding between secretion and absorption. Professor Thomson makes some curious remarks about "gland inclusions." states, "The use of this expression is convenient. It commits us to no definite view or to their nature." expression has a very definite meaning to me.

Professor Thomson appears to have been influenced by work of one Beiling (1905), who denies that the endometrial glands have a secretory function. Moreover, he states the uterine glands fail to react to mucus tests. I would Professor Thomson to test the accuracy of this last statement himself.

I refrain from further criticism. My object in writing letter is to prevent, if I can, an impression getting abroad as would be inevitable if Professor Thomson's paper is taken seriously—that gynaecological anatomy and physiology are vague and medieval.—I am, etc.,

Liverpool, Jan. 12th.

W. BLAIR BEL

SIR.—In view of the great interest now being taken in whole subject of birth control, Professor Arthur Thomson's address to the Oxford Medical Society is very opportune, the medical profession are to be in a position to give the advice to their patients on the practical aspect of conception control—and the public are now looking to the profession to do this—much more serious scientific study of the subject necessary. Hitherto it has been sadly neglected, and Professor Thomson is all the more to be congratulated, therefore, for having taken it up. I sincerely hope that he will continue his investigations.

The gist of his address is to suggest that sex intercourse has a distinctly beneficial effect upon the female through absorption of the male ejaculate, and that this absorption takes place through the glands of the uterine mucosa. concludes by suggesting that the use of contraceptives may be injurious "by depriving the female of certain secretions which may exercise a far-reaching influence on her economy." This raises a very important practical point. Professor Thomson's final suggestion is altogether too vague to rest at that, and I hope that he or others will follow it up. There are different forms of contraceptives and Professor Thomson does not distinguish between them. Not all contraceptive devices prevent the semen from entering the uterus. Thus, quinine pessaries, which are very widely used, aim at nothing more than destroying vitality of the spermatozoa. It does not follow that the ingredient, quinine, would have any deleterious action on the secondary effect of the seminal fluid, to which Professor Thomson draws attention. Moreover, the use of such material as the rubber cap, the tampon, or the sponge, whilst pro-

ing the semen from entering the uterus, do not prevent absorption through the mucous membrane of the vagina. It is quite possible that as much, or more, absorption takes place there as in the uterus. Assuming, then, that sex intercourse is beneficial to the female as well as to the male, it seems reasonable to suggest that it is better to have intercourse in marriage, even if the full advantage of it is not obtained, than to go without it altogether, or to fall back upon *coitus interruptus*. For those are the only alternatives to contraceptives open to those who feel, for various reasons, that they ought not to have more children. Better half a loaf than no bread.

But however this may be, if we look at the matter from the point of view of the poor overburdened mother with more mouths to feed already than she knows how to provide for, I think we may assert without fear of contradiction that she will gladly forego the benefit of coitus for herself so long as she is able to escape from the evil of too frequent conception and excessive maternity, and at the same time be able to satisfy her husband.—I am, etc.,

Leicester, Jan. 15th. G. KILLICK MILLARD.

ENCEPHALITIS LETHARGICA AND MENTAL DEFICIENCY.

SIR,—In a paper in the current number of the *Journal of Mental Science* Dr. G. A. Audon refers to the "extraordinary moral changes which not infrequently follow an attack of encephalitis lethargica." He states that such children often prove a nuisance at school and at home, but that they cannot be dealt with under the Mental Deficiency Act.

May I say that in Scotland such cases are dealt with under the Mental Deficiency Act? I have two such cases in this institution, and Dr. Clarkson informs me that he has several at Larbert. No doubt these cases are not just the class of defectives for which the Act was intended, but some of them fully require institution treatment, and it is obviously most desirable that they should be treated in a certified institution for mentally defective children rather than in an asylum or mental hospital for adult patients.

My two cases are quite unfit to be at home, but are attending the institution school. They are both certified by outside doctors as "moral imbeciles" on account of vicious propensities apparently resulting from their illness. I think it would be better to certify such cases, however, as "feeble-minded," even although their defect is more moral than intellectual. Their aberrant conduct is a symptom of mental defect acquired "at an early age," which renders them "incapable of receiving proper benefit from the instruction in ordinary schools." This brings them within the scope of the definition given in the Act of "feeble-minded persons," with the exception that in the Act the word "permanently" is used—"appear to be permanently incapable," etc. It does not at present appear to be possible to say whether or not the defect is of a permanent nature, but it is so obviously desirable that cases of the kind who may be likely to benefit by institution training, and who may be capable of attending school in an institution, though not an ordinary school, should be sent to a certified institution for children rather than to any other existing kind of institution or hospital, that I do not think medical men need hesitate to certify such cases under the Act. This is desirable, not only from the point of view of the child's interest, but as the best means of gaining knowledge regarding the prognosis in such cases when placed in favourable educational surroundings.—I am, etc.,

W. B. DRUMMOND,
Medical Superintendent.

Baldovan Institution for the Treatment and
Education of the Feeble-minded,
Dundee, Jan. 10th.

HOSPITAL POLICY.

SIR,—Thanks to Mr. Bishop Harman's effective co-operation, we now know that the letter (*BRITISH MEDICAL JOURNAL*, December 24th, 1921, p. 1095) signed "Chairman of the Hospitals Committee" did not contain an authoritative judgement of this Committee, but only certain propositions that had had the good fortune to secure Mr. Harman's personal approval. It was in the hope of banishing any doubt on this point that my letter (*BRITISH MEDICAL JOURNAL*, January 7th, p. 35) was written. Whether the propositions were original or borrowed is surely immaterial. The essential point is that the letter, though signed by the

"Chairman," was not an official communication authorized by the Committee.

I confess that in the swift and commanding tones of Mr. Harman's sentences I had not recognized the resolution accepted at Newcastle, and I venture to think that if the views of the Association are to be publicly announced, they had better be announced in the terms formally adopted rather than in the free translation effected by a challenging individual notice. Further, unless my memory deceives me, the resolution in question has no official authority or status, for it was taken on an issue on which the representatives had not been instructed by their constituencies. Perhaps I ought to have made a further speech. Mr. Harman seems to reproach my silence, and his own example, I gratefully allow, has been consistently opposed to such abstinence. In any event, not even the British Medical Association has authority to change the meanings of words, and current controversies show plainly that laymen, I fancy without exception, continue to use the term "voluntary hospital" in the sense described in my letter and recognized by Mr. Harman as based upon an accurate historical statement. To take an old-established word and to try to impose upon it a new definition is, to put the position mildly, a confusing and arbitrary procedure, and the promoters of such a policy cannot escape the reproach that they are posing in the stolen clothing of their predecessors. If the thing is to be changed, let the name also be changed.

With his natural generosity Mr. Harman will, I am sure, forgive my failure to trace in his letter the dignified inspiration which he now describes as its true source. And he will be all the more ready to do this when in reference to my own letter (a much more recent document) he recognizes that, not, as he suggests, a want of courage, but a desire for accuracy, prevented me from describing as one of the features of the "voluntary hospital" a system of "gratuitous nursing." My concern was with things as they are, and had I described a non-existent condition I should have failed to merit the compliment for historical accuracy which Mr. Harman has so graciously placed on record. This slight slip on his part will be the more readily excused seeing that but for it the readers of the *JOURNAL* might never have had the advantage of his penetrating though somewhat irrelevant observations on the respective merits of the three-legged and the four-legged table, and might never have realized that these strictly utilitarian and prosaic supports may be yoked to the service of high imaginative effort.

I will make no attempt to rival Mr. Harman in his forecast of the fate either of the "poor" or of the hospitals. Time, it is true, plays strange pranks with words, and it may be that in some distant future our hospitals will boast at one and the same time that they are "voluntary" and that they are not supported by voluntary contributions. Then, indeed, Mr. Harman will appear to be justified and will enjoy a posthumous fame as one of the earliest preachers of the doctrine that in a "voluntary hospital system" neither voluntary services (save those of management) nor voluntary contributions merit an essential and abiding place. The one risk is that there may appear some still more radical advocate, who will urge (why not?) that managers, equally with doctors, should be paid for their services, and in such circumstances it is to be feared that history will label the Bishop Harman of the twentieth century a mere Laodicean opportunist and a stoker of feeble and ineffectual fires.—I am, etc.,

London, W., Jan. 16th.

C. O. HAWTHORNE.

SIR,—Mr. Harman's continued efforts to belittle the Cave verdict on the Leicester motion will deceive no one. Clearly the Chairman of the Council and the Representative Body did not deliberately and publicly snub the Cave Committee out of mere love of mischief. Ill judged as was that action, it was forced upon them, having adopted the Leicester motion, because it was obvious that the latter was wholly incompatible with the Cave report. No one, as alleged by Mr. Harman, has ever suggested anything so absurd as that paragraph 50 was "the quintessence" of that publication. It was, however, the particular portion thereof which dealt emphatically and authoritatively with the matter in debate, though of course many more considerable problems are involved in the study of hospital maintenance and finance, and was in fact penned, no doubt with full sense of responsibility, after twenty-eight meetings and examination of ninety-three expert witnesses. Nothing apparently would convince Mr. Harman but a promiscuous distribution of damnation of the Leicester motion over the whole document.

Mr. Harman has never replied to my inquiry: How many staffs of hospitals have so far commended this motion to their committees, and what happened if they did? Personally I believe that for all practical purposes the Leicester proposal is as dead as Queen Anne. We are asked to demand that an unnamed portion, which if we may judge by precedent will start at 10 per cent. and rise rapidly to 25 per cent., of a large number of payments collected by laymen from laymen for exclusively lay purposes—namely, hospital maintenance—shall be appropriated by the medical staff, and already the plea of a fund for altruistic purposes is abandoned. The precarious profits of this adventure are frankly designated by Mr. Harman "remuneration," and avowedly for the staff themselves. Whether payments in kind are to be included with those in cash is not specified, but clearly, since they equally contribute towards maintenance, our claim upon such is equally justified. Therefore we may visualize a weekly distribution of eggs, butter and garden produce by the still honorary committee among the sometime honorary medical officers. Now the action of the Representative Body in endorsing such a claim as the Leicester motion is strictly comparable to their action in December, 1912. Both exhibitions of folly, as I consider it, would have been avoided by first consulting a few competent laymen. I offer to the second the same strenuous opposition that I did to the first, and I hope, and indeed believe, with more success. Otherwise the result will be as before, we shall be, figuratively, kicked downstairs again.

I have, however, but little fear of such catastrophe. The Leicester motion has been utterly rejected by the staffs of Scottish hospitals; even in London the change in opinion with regard to it is already quite remarkable, and its final extinction in the county hospitals is, I believe, assured. It is a pity that it was ever invented, as it is calculated seriously to prejudice the profession in the eyes of the public, whose opinion upon it is, without doubt, accurately represented by paragraph 50 of the Cave report.—I am, etc.,

Chichester, Jan. 11th.

G. C. GARRATT.

"STIMULANTS."

Sir,—Dr. Campbell's letter (*BRITISH MEDICAL JOURNAL*, December 24th, 1921, p. 1095), in reply to my criticism of his classification of alcohol as a "stimulant," should not be allowed to pass unanswered. The question at issue is whether alcohol is rightly regarded as a "stimulant" or as a "narcotic." Dr. Campbell is obliged to admit that it may act as a narcotic, but he declares it to be a "glaring fact—that under certain conditions alcoholic drinks are stimulating." The review issued by the Advisory Committee of the Central Control Board (Liquor Traffic), to which I alluded in my previous letter, appears to embody the clearest and most dispassionate study hitherto made of the action of alcohol; and the names of the members of the Committee are sufficient guarantee that its conclusions are of scientific value. I notice that Dr. Campbell makes no reference at all to the findings of this Committee, which are in direct conflict with his views.

Dr. Campbell asks whether I seriously maintain that in states of exhaustion alcohol may not have a "temporary reviving—that is, stimulating—effect," and instances the case of "an aged subject slowly and painfully recovering from a severe attack of influenza," and that of a man who habitually consumes two bottles of whisky a day, and has experienced several hours of unaccustomed abstinence. The proper reply to this question depends entirely upon what we mean by the terms "stimulant" or "stimulating." There is no doubt that alcohol commonly produces a sense of well-being, and in the words of the Advisory Committee it is this effect "which perhaps more than any other is the secret of its charm, its well-nigh universal attraction for the human race." This effect is primarily mental, and is shown to be due to "a blunting of the sensibility to the small aches and pains and a thousand hardly distinguishable sense-impressions which, except to those in perfect health, contribute to tip the balance of bodily feeling-tone to the negative or unpleasant side." No doubt the aged subject of influenza might feel his painful recovery lightened for a brief period by the effect of the glass of champagne, but I maintain that it is not true in the scientific sense to say that this is due to a "stimulating" action of the champagne. Is it not due to its blunting action on the highest centres, so that for a brief period the patient is not so conscious of his aches and pains? So given the use of alcohol may be properly justified, but we should acknowledge its action to be that of a sedative, not a stimulant.

As regards the two-bottles-of-whisky man, here the confusion of terms is more obvious. The two-bottle man would undoubtedly be much cheered by the advent of another bottle after an unaccustomed spell of abstinence; but surely it is not true to say that this sense of comfort is due to a "stimulant" action of alcohol. He craves for the comforting sedative effect of his favourite narcotic, exactly as the opium-eater does if deprived of opium.

In my time as a medical student we used to be taught that alcohol had a brief stimulant action, but even this is denied by the latest research. The true explanation of the apparent brief stimulation, on the uterine side, has already been stated. The quickening of the heart beat that is common after a moderate dose of alcohol is also shown to be a depressant rather than a stimulant action of the drug. To quote the Committee: "The acceleration of pulse appears to be due to depression in degree of the reflex cardio-inhibitory tone which normally restrains the heart beat." "When it (that is, alcohol) appears to promote recovery from fainting, it probably acts simply by virtue of its irritant action on the mucous membrane of the mouth and throat. . . . Its use in these circumstances is therefore comparable with that of smelling salts." "In this direction, as in others, the popular idea that it is a 'stimulant' proves on examination to be scientifically untenable."

Is Dr. Campbell prepared to prove that the Advisory Committee has erred in its conclusions?—I am, etc.,

Alderley Edge, Cheshire, Jan. 3rd.

E. WEATHERHEAD.

TREATMENT OF TUBERCULOSIS WITH COLLOID CALCIUM.

Sir,—The results obtained by Dr. Prest, as published in your issue of January 14th, should stimulate others to try this method of treatment in conjunction with other therapeutic measures. One knows that nature will utilize calcium in her processes of repair if circumstances are favourable, but how can we explain the many failures of the past when not only calcium salts have been given by mouth but cow's milk, which contains an abundant supply of that mineral, is equally imbibed with faith and hope?

Calcium is present in the body in two forms—(1) fixed, (2) ionized—and it is in the latter state that calcium is "rushed up to the front" in times of emergency, the former remaining as a reserve "at the base" to be drawn upon when the mobile variety is exhausted. The calcium in cow's milk is in a non-ionized form.

We believe that the ductless glands are the regulators of this traffic, and can be divided into two main groups—(1) the calcium excretors, consisting of the genital glands and posterior pituitary; (2) calcium retainers, such as thymus, anterior pituitary, thyroid and parathyroid.

Broderick studied caries of the teeth from the point of view that caries was due to a decrease in the alkalinity of the saliva brought about by want of balance in the secretion of the ductless glands. But what brings about this want of balance? One answer is toxæmia.

The late Rupert Farrant examined the condition of the thyroid gland post mortem in 700 cases of acute disease, and could group these diseases according to their effect on the thyroid. Among other diseases (acute infections) he found that acute tuberculosis produced an acute or complete degeneration of the thyroid, whilst chronic tuberculosis gave rise to a colloid or chronic degeneration. If these observations are correct, is it not permissible to suggest that the endocrine glands, being poisoned by toxins, are only functioning feebly, and that therefore calcium, even if it can be ionized in the body, is not seized upon by those ductless glands whose work it is to distribute calcium to the scenes of action?

It seems as if Dr. Prest is taking a step in the right direction, in that tuberculous patients are in great need of ionized calcium, and if we can give it to them in a form that they can absorb, the lesion, if not too extensive, might heal, toxin production would be reduced, so that the ductless glands which regulate metabolism would, with renewed activity, build up the tissues, and the antibody mechanism could then assert itself fully.

It goes without saying that the usual treatment by fresh air, feeding up, and exercise, as well as oral hygiene and the psychological side, should not be neglected.

For two reasons I do not enthusiastically advocate the administration of glandular products together with Dr. Prest's form of treatment—first, because I have had no experience of

this form of medication in this particular disease, and secondly, because at present these products are not standardized and one knows so little as to what combinations are likely to be of avail; but I think that it is worth while to try either a single one, such as parathyroid extract, or a pluriglandular combination in conjunction with colloidal calcium. — I am, etc.,

A. D. SYMONS, M.D., M.R.C.S., D.P.H.,
Assistant M.O., City Isolation Hospital and Sanatorium.
Bristol, Jan. 16th.

HELIO THERAPY AND THE WOLFRAM ARC REACTIONS.

SIR.—After reading Dr. Bernard Hudson's most interesting article on "Mountain climates in health and disease," in your issue of November 5th, 1921, it has occurred to me that the close analogy between his results from heliotherapy and my own from the use of the rays from the wolfram arc, in war service and private practice, might be of some interest.

It has long been established that the wolfram arc gives off an extreme volume of ultra-violet rays, electro-magnetic rays, and it is generally known that the rare metals are radioactive. These facts being acknowledged, there is at once established a comparison with the sun's rays.

The marked analgesic effect of wolfram rays in about one and a half to two minutes on, say, a recently reduced dislocation, a severely sprained ankle, acutely inflamed dental socket, acute frontal neuralgia, or acute lumbago, is a result only to be believed possible by actual demonstration. Many other painful conditions are capable of being relieved in the same way—for example, varicose veins and ulcers and eczema. Dr. Hudson claims similar results from the sun's first reaction, and I believe all who have had an extended use of the wolfram rays will agree that on this point the two reactions are similar.

In regard to pigmentation, here again the results are identical, fair or reddish people reacting much more quickly than dark; the concentrated intensity of the wolfram rays causes reaction much more quickly, anything over one minute's exposure producing pigmentation. In the absorption of adhesions I have had similar results.

Dr. Hudson refers to the general improvement in the patient under heliotherapy; it has frequently been my experience for patients to exclaim voluntarily, after, say, fourteen days' treatment with wolfram rays, how much improved they are in general health.

After using the wolfram rays continuously for four and a half years, with about 30,000 administrations in the N.Z.M.C. and a large number in private practice, my experience has been as follows: (1) The rays are extremely bactericidal; (2) they are markedly analgesic; (3) they produce tissue in the healing of wounds of a character and vitality quite different from ordinary scar tissue—that is, more natural; (4) they have never to my knowledge caused any harm to those treated or to those who apply them properly. — I am, etc.,

Edw. JAS. DECK, M.R.C.S., L.R.C.P.,
Ex-Captain N.Z.M.C.
London, W.1.

PROFESSIONAL SECRECY AND MEDICAL EVIDENCE.

SIR.—Dr. Brend's contribution on this subject in your issue of January 14th is highly interesting, and is written with that lucidity and clarity always so characteristic of his pen. He has laid down the position of English law relating to medical privilege, which I am not disposed to question or dispute; his conclusions, I trow, will nevertheless be considered more academic than just.

Perhaps it is true to say that no body of men are the recipients of such grave and profound confidences as general practitioners of medicine, and I am confident that the general practitioners will not be content to abide by the recent rulings in the courts, but, on the contrary, they will instruct their Divisions to insist upon the Representative Meeting emphatically declaring a very definite and decisive policy on the subject. Indeed, it seems to me, since medicine is becoming so rapidly and increasingly under public control, it is of paramount importance to the successful administration of such State medicine that medical privileges should be maintained.

It is surely obvious that if the public are possessed of any doubts in their minds concerning professional secrecy, the result can only be a disastrous handicap to the doctor in securing an accurate history, and in consequence will seriously

mitigate against the successful detection of disease, as well as efficiency in treatment.

Professional secrecy should be maintained essentially in the interests of the State and the community, access to the treatment of disease being absolutely free and unfettered, and the promotion of justice is not at all likely to be defeated thereby. — I am, etc.,

Bournemouth, Jan. 16th.

WALTER ASTEN.

MIDWIVES AND OPIUM.

SIR.—Referring to the report of the Central Midwives Board and the use of opium by midwives, I should like to state that opium, in reasonable medicinal doses, is not a dangerous drug, and can result in no harm to mother or child when given at a confinement except in a case of severe nephritis, in which case a qualified midwife will send for a doctor, if for no other reason than her own protection.

It is a great mistake to tie up midwives with too many and too stringent rules, as it limits their power of action and their usefulness, and has a decided tendency to turn patients away to "Gamps," of whom we have still a multitude.

I am not aware that midwives use pituitrin, except under a doctor's direction; but if so it seems unwise with their present knowledge, as it is by no means so safe a drug as opium. I have thirty years' experience of the use of opium for horses, cattle, and people of all colours, ages, and conditions, and have never had cause to regret its use where necessary, even in patients with advanced heart disease, or infants. It is still the most valuable drug we possess. — I am, etc.,

Northampton, Jan. 8th.

ABRAHAM PORTER, M.D., Ph.C.

No. 1 CASUALTY CLEARING STATION.

SIR.—The achievement of No. 1 Casualty Clearing Station was probably unique, amongst medical units, in the history of the war. On August 4th, 1914, orders were given to mobilize the "clearing hospital," which was afterwards officially designated No. 1 Casualty Clearing Station. On August 16th it embarked at Southampton, under sealed orders for France and proceeded at once towards Mons, where it commenced work during the strenuous times consequent on the famous retreat. The late Colonel F. H. Symonds, R.A.M.C., was the first commanding officer. After having had many locations and vicissitudes throughout the whole period of the war, it finally laboured to keep up with the British advance which began about August 8th, 1918. The casualty clearing station was last under canvas at Escaudoeuvres, near Cambrai, and had the signal honour of moving into Mons and taking charge of the civil hospital on November 14th, 1918, just the day before General Horne made his formal entry into the town. The "Hôpital Civil" had been occupied by the Germans during the war as a Kriegslazarett, and when taken over by the medical officers of the casualty clearing station (seven in number, including the then commanding officer, Lieut. Colonel E. M. Cowell, R.A.M.C.) it immediately became crowded with starving and (in many cases) diseased men belonging to the British Army who had been prisoners in Germany, and who were not very fit subjects for the epidemic of influenza which was prevalent at that time. — I am, etc.,

Belfast, Dec. 27th, 1921.

S. W. ALLWORTHY.

THE ANTE-NATAL TREATMENT OF CONGENITAL SYPHILIS.

SIR.—I have read with interest Mr. Adams's criticism, in the JOURNAL of January 14th, page 56, of my communication to the British Medical Association at Newcastle on "Ante-natal treatment of congenital syphilis," criticism which I am specially pleased to see, as it is, at least so far as I am aware, the first reference by Mr. Adams to any work of his predecessors in this field. He however has confused the issue. In my communication the discussion was of ante-natal *versus* post-natal treatment of congenital syphilis, and I concluded, from my own work, from that of the French pioneers in the field, and from the more recent work of Mr. Adams himself, that ante-natal treatment gives far and away the best results; a conclusion substantiated by his latest figures. So far as I can gather from Mr. Adams's several communications he always practises ante-natal treatment, and thus merely carries out what I and others have been teaching for years. He makes no mention of post-natal treatment, pure and simple.

His answer to my query regarding the time of election for treatment of syphilitic mothers is beside the point. He states his practice but without giving reasons for the faith that is within him. What I desire to know is, when (before pregnancy comes or during pregnancy) is treatment most efficient so far as the health of the unborn child is concerned? My own work has led me to the view that more certain results, and apparently with greater ease, are obtained by treatment during pregnancy; but my experience is limited, and I feel for records of definite observations in support of or against such a view. I am, etc.,

CLARENCE W. JONES.

EDWARD FISKE.

Obituary.

SIR JOHN KIRK, G.C.M.G., K.C.B., M.D., F.R.S.,

President of the Royal Geographical Society.

SIR JOHN KIRK, the companion of Livingstone on some of his journeys, died at Sevenoaks on January 15th in his 90th year. He had been ill for a long time.

Sir John Kirk was not only a keen scientific worker but an ardent explorer, and his life bade us with a distant past. He was a son of the manse, and was born at Arbroath, Forfar, on December 19th, 1832, and as a schoolboy he was fortunate in finding scope for his bent towards natural history, and particularly in botany, which doubtless influenced his later career. He pursued his medical studies in Edinburgh, where he graduated M.D. in 1857. The Crimean war was then in progress, and young Kirk saw active service in Turkey during the campaign, where, with a volunteer party of young Scottish medical men, he rendered help at one of the base hospitals in the Dardanelles. Having tasted this experience of foreign travel and adventure, it is not surprising that he should be attracted to share in African exploration under the great Livingstone. Sir Richard Macchison, the distinguished president of the Royal Geographical Society, when announcing the choice of staff for the Zambesi expedition in 1888, said, "Dr. Kirk of Edinburgh, an accomplished botanist, zoologist, and physiologist, also accompanies the expedition."

During five years at least he occupied a foremost place in the exploration of the Zambesi region, including especially the tracing of the river Boroma and part of lake Nyassa. He was at this time Livingstone's chief lieutenant, but there was no question as to who was the leader. Livingstone, himself a medical man, was a personality of outstanding powers and gifts, and it was natural that his work should overshadow the attainments of his colleagues, though he did not belittle them. Whether Kirk of his own initiative would have accomplished the same results without the guidance of his great companion is difficult to say, but there can be no question that Kirk rendered signal service to this expedition.

Little record seems to be available as to his scientific researches, though we find that he, as the naturalist of the party, demonstrated to the Royal Geographical Society in April, 1884, a collection of fossil animal bones. There is no mention of any human remains, but pieces of pottery were found which were regarded as showing the antiquity of man in that region, though the animals were of the same type as those now known. His medical work does not come into the prominence, but with Livingstone already experienced in the study and treatment of tropical diseases there was not much scope for Kirk, who was engaged as a naturalist and not as a medical officer. At the same time he was the medical attendant to Mrs. Livingstone in her last illness, and at risk to his own health refused to leave Livingstone when he was attacked by illness at that time.

The next stage in Kirk's career found him at Zanzibar, where he was appointed Government medical officer in 1885. He does not appear to have remained long in this position, for, like Livingstone, he was destined to figure more prominently in administrative work than medical practice. Thus we find him during fifteen years first Assistant Consul and then Consul-General and Resident of Zanzibar. It was hoped that in this position he would be able materially to help Livingstone in the matter of supplies and communications. The proverbial uncertainty of African trade routes in those days, with the constant menace from the slave-raider, made this difficult. Some misunderstanding with Livingstone ensued, but was happily removed.

At Zanzibar he was the constant advisor and friend of the various explorers who entered Africa from the east coast during his term of office. The political importance of

Zanzibar at that period, before the delimitation of spheres of influence between the chief European powers, must be remembered. German competition and intrigue resulted in the assigning to Germany of the great territory to which Zanzibar was the door of entry. In all these negotiations Kirk appears to have acquitted himself with great tact and with a desire to uphold the best interests of his own country and the welfare of the native races of Africa.

That the value of his work was appreciated was shown by the bestowal upon him of decorations and academic honours. He was created a K.C.M.G. in 1881, G.C.M.G. in 1886, and K.C.B. in 1890. In 1862 he received the Patron's medal of the Royal Geographical Society; afterwards he became foreign secretary of the Society, an office he retained until 1910. He was an honorary LL.D. Edin., D.Sc. Cantab., D.C.L. Oxon., and was F.R.S. and F.L.S.; he was an honorary Fellow of the Royal Society of Tropical Medicine and Hygiene, and a corresponding member of the Zoological Society.

When the Brussels Conference was held in 1889 to deal with African affairs, and specially the slave trade, Kirk, as was most fitting, was a British plenipotentiary, and took a share in the inclusion of clauses relating to the African spirit trader, which were inserted at the instance of Great Britain, and have rendered famous the Brussels General Act of 1890.

One more official service was rendered by Kirk when as a British Commissioner he was sent to inquire into serious disturbances in Brass, West Africa, in 1895. His wide experience of African affairs stood him in good stead in this inquiry, and it must have come as a shock to him that in spite of the high ideals of the Brussels Act he was forced to conclude that in the district visited "the last four centuries of contact with Europeans and European trade have degraded rather than elevated or improved the people."

He married in 1867 Helen, daughter of Charles Cooke, and for many years he lived in a peaceful home at Sevenoaks, patient and courteous, a splendid type of an English gentleman. For a considerable time he was practically blind, and the death of Lady Kirk in 1914 was a serious loss to him. He leaves one son and three daughters.

The medical profession may well be proud of two such distinguished representatives as Livingstone and Kirk. Undoubtedly they were largely responsible for laying the foundations of the scientific work, medical and other, which has been a prominent feature of the explorers and administrators of Africa. High ideals are as important as detailed discoveries such as those which have been made with brilliant results by British medical experts of to-day representative of the Tropical Schools, of the Royal Society, of the Government, and of the Missionary Societies. Kirk took his share in blazing the trail which others have followed with infinite devotion and with the loss of valuable lives. There are still many secrets to be unfolded and pests to be conquered in the African continent, and the memory of one of the pioneers, who has died full of age and full of honours, should spur on many a younger worker to take part in this fascinating exploit.

E. MANSEL SYMPSON, M.D.,

Surgeon, Lincoln County Hospital.

THE announcement of the death of Dr. Edward Mansel Symptom, of Lincoln, will be received with great regret by a large circle of friends. He was the only son of the late Mr. Thomas Symptom, surgeon to the Lincoln County Hospital, and was born in 1860. He was educated at Lincoln Grammar School, Shrewsbury School, Gonville and Caius College, Cambridge, and St. Bartholomew's Hospital; there he held the offices of both house-physician and house-surgeon. He graduated M.A., M.B., B.Ch. at Cambridge in 1887, and proceeded M.D. in 1890. Soon after graduation he settled in practice in Lincoln, and became surgeon, first, to the Lincoln General Dispensary, and afterwards to the Lincoln County Hospital. He contributed a number of papers, chiefly on surgical subjects, to the medical journals, and took an active interest in the British Medical Association. He was secretary of the Section of Diseases of Children at the Annual Meeting of the Association in 1897, vice-president of the same section at Cheltenham in 1901, and was president of the Association in 1906-7.

His hobby was archaeology, for the study of which his native city afforded many opportunities; he wrote a historical and topographical history of Lincoln, contributed the article on Lincolnshire to the *Cambridge County Geographies*, and

was editor of *Memorials of Old Lincolnshire*. He also edited *Lincoln Notes and Queries*, was co-editor of the Associated Architectural Societies' reports and papers, and honorary local secretary of the Society of Antiquaries. He took an active part in the life of Lincoln, was J.P. for the city, had been sheriff, and held a commission as honorary lieutenant-colonel R.A.M.C.(T.F.). He married the daughter of the late Mr. Joseph Knight, a well-known antiquarian and journalist.

THE LATE SIR GERMAN SIMS WOODHEAD.—A service in memory of Sir German Sims Woodhead was held in the Memorial Hall, London, on January 11th. The Rev. Principal W. B. Selbie, of Oxford (formerly minister of the church at Cambridge with which Professor Woodhead was associated), presided, and a large gathering included Sir Thomas Barlow, Sir F. W. Mott, and Mr. McAdam Eccles, as well as representatives of religious and temperance organizations. Sir Thomas Barlow, in a brief address, said that he first met Sims Woodhead forty years ago. He changed very little either in physique or character; at the time of their first association he was somewhat round-shouldered, rather pale, with a serious, thoughtful face and a very engaging manner, which, although he was a man of few words, showed that at the background of his personality there was not only a wide intelligence but a real goodwill to his fellows. He was then in charge of the pathological department of the Children's Hospital in Edinburgh, where his attention was early drawn to the subject of tuberculosis. One branch of this subject—namely, the dissemination of tubercle by cow's milk—was at that time little more than a speculation, and Woodhead subsequently threw a flood of light upon it. From Edinburgh he went to London, and from London to Cambridge, where he spread his abundant energies over many other matters than those relating to his professorship. No labour was too exacting for him, and his counsel and advice were at the disposal of all his junior teachers and assistants. There was no doubt that his health was broken and his life shortened by his unselfish devotion to his teaching duties, and still more by his indefatigable war labours. Sir Thomas Barlow concluded by expressing the opinion that the recognition of Woodhead's work came late; his zeal in temperance reform was perhaps a disability, but he (Sir Thomas) never heard a syllable nor saw a sign which would imply that Woodhead felt that his personal claims had been ignored. Mr. McAdam Eccles added a few words of tribute to "a great man, but one whose modesty was such that in his own eyes he was a little child." The Rev. Courtenay Weeks, on behalf of the National Temperance League, expressed its feelings of loss, and Principal Selbie closed the meeting after reciting a few instances of the late professor's love for his fellow man, and in particular his interest in lonely undergraduates at Cambridge.

Dr. JOHN SIMPSON died at his residence in Belfast on January 11th. He was educated at Queen's College, Belfast, and, after a brilliant career as a student, graduated M.D.Q.U.I. in 1879. He showed special interest in the treatment of diseases of the chest, and as early as 1880, with the assistance of Dr. H. S. Purdon, he opened the Belfast Provident Institution for Chest Diseases, which was the forerunner of the Forster Green Hospital at Fortbreda Park. He built up a large general practice, and was widely respected alike for his personal character as for his qualities as a physician. His only son was junior surgeon in the ill-fated *Titanic*, which was lost on her maiden voyage across the Atlantic. Dr. Simpson was a former chairman of the Belfast Division of the British Medical Association, and took great interest in its work. He was a devoted Presbyterian, an elder of the church, and a convinced but moderate Unionist. He is survived by his widow and three daughters.

Dr. WILLIAM GIBSON, of Campbelltown, Argyllshire, died on January 13th at the great age of 98. He graduated M.D. Edin. in 1854, and in the same year took the diploma of L.R.C.S. Edin. Only fourteen months ago he retired from public appointments which he had held for sixty-five years. Dr. Gibson was elected a member of the British Medical Association as long ago as 1870; he resigned in 1920 owing to ill health; he had thus been a member of the Association for exactly half a century. He is survived by a married daughter.

Dr. PATRICK JOBSON HENDERSON, who died recently at Jansenville, South Africa, was educated at Aberdeen University, and graduated M.B., C.M. in 1896. After practising in Cumberland he went out to South Africa during the Boer war, serving as a captain in the Cape Medical Staff Corps; after the war he remained and went into practice.

WE regret to record the death of Dr. JOHN GALLOWAY, which took place at Port Elizabeth on November 22nd. He graduated M.B., Ch.B. at Glasgow in 1890, and took the D.P.H. in the same year. He went to South Africa in 1898, and had practised at Port Elizabeth ever since. He was for some years medical officer of health for the town.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

SIR ARTHUR SHIPLEY is announced to give a course of lectures and classes on the history of the biological sciences in the Arts School on Tuesdays and Thursdays at noon during the Lent and Easter terms.

Diploma in Tropical Medicine and Hygiene.—The following candidates, having satisfied the examiners, are entitled to the diploma: J. D. Gazder, P. M. Nanavate, W. W. Pratt, J. P. Rosha, J. Singh.

UNIVERSITY OF LIVERPOOL.

THE following candidates have been approved at the examination indicated:

D.P.H.—Mary A. S. Deacon, G. I. Griffiths, Mary E. Illingworth, Phoebe A. Ince, J. B. Murphy, A. E. Richmond, W. Williams.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY council was held on January 12th, when Sir Anthony Bowlby, President, was in the chair.

Issue of Diplomas.—Diplomas in Public Health were granted, jointly with the Royal College of Physicians, to 17 candidates; diplomas in Tropical Medicine and Hygiene to 17 candidates; and diplomas in Psychological Medicine to 15 candidates.

The War Office Collection.—The Council decided upon the architectural details needed for the proper display of this large collection, which is now entrusted to the care of the College.

Hunterian Oration.—The oration for 1923 will be delivered by Sir John Bland-Sutton.

The Services.

COLONEL ARTHUR M. CONNELL, late Officer in Command, 3rd Northern General Hospital, was presented by the Belgian Consul at Sheffield, on January 12th, with the insignia of the Order of St. Leopold, awarded to him by the King of the Belgians.

DEATHS IN THE SERVICES.

Major-General Sir Walter George Augustus Bedford, K.C.M.G., C.B., Army Medical Service (retired), died at Eynsham, Oxon., on January 8th, aged 63. He was the son of the late Vice-Admiral G. A. Bedford, R.N., and was born at Rathmullen, co. Donegal, on October 24th, 1858. He was educated at St. Bartholomew's and at Durham University, where he graduated M.B. in 1880; he took the M.R.C.S. in the same year. He entered the army as surgeon on February 5th, 1881, he attained the rank of colonel on September 19th, 1908, was placed on half-pay on completion of four years' term of service in that rank; he was restored to full pay on promotion to surgeon-general on January 1st, 1914; this title was changed to major-general in 1918. He retired on October 29th, 1918. After filling the post of adjutant of the R.A.M.C. dépôt at Aldershot, he was appointed deputy assistant director-general at army headquarters on January 11th, 1899, but before the end of the year was sent to South Africa as staff officer to the principal medical officer in the South African war. There he took part in operations in the Transvaal, Orange River Colony, and Cape Colony, was mentioned in dispatches in the *London Gazette* of April 16th, 1901, and received the Queen's medal with three clasps, and the C.M.G. He afterwards served as P.M.O. in South China, 1908-11, as D.D.M.S., London district, in 1912-13, D.D.M.S., South Africa, in 1914; then as D.D.M.S., Southern Command; in 1914-15, and as director of medical services in the Mediterranean and Egyptian Expeditionary Force in 1915-16, when he was mentioned in dispatches in the *London Gazette* of July 13th, 1916, receiving the C.B. on June 3rd, 1916, and the K.C.M.G. on June 3rd, 1918. From 1916 till his retirement he was D.D.M.S. of the Northern Command. Durham University conferred on him the D.C.L. in 1920. In 1880 he married the daughter of the Rev. D. J. Drakeford, by whom he had one daughter.

Lieut.-Colonel Kanta Prasad, Bengal Medical Service (retired), died of heart failure at Benares on December 16th, 1921, aged 61. He was a Punjabi, born at Meerut on May 17th, 1860, and was educated at Edinburgh, where, after taking the Scottish triple qualification in 1886, he graduated M.B. and Ch.M. in 1887, and M.D. in 1913. Entering the I.M.S. as surgeon on March 31st, 1888, he

became lieutenant-colonel on March 31st, 1908, and retired on June 3rd, 1913. He served on the North-East frontier of India in the Manipur campaign of 1891, receiving the frontier medal with a clasp; on the North-West frontier in the Isazai campaign of 1892, and in the Tirah campaign of 1897-98, on the Malakand, and in operations in Bajaur and the Mohmand country receiving the medal with two clasps. Most of his subsequent service was spent in civil employ in Burma. He rejoined for service in India during the recent war from January 29th, 1915, until September 9th, 1921. He received the Kaiser-i-Hind medal, 1st class, on June 4th, 1917. He was the author of a work on *Health and Mortality among Educated Indians*, 1913.

Medical News.

SIR JOHN ROSE BRADFORD, honorary secretary of the Lord Lister Memorial Fund, has intimated to the Marylebone Borough Council that the committee of the Fund has accepted the council's offer of a site for the memorial to Lord Lister at the north end of Portland Place. The work will be carried out by Sir Thomas Brock.

THE *Journal of the American Medical Association* for December 24th, 1921, contains a personal appreciation of Sir William Osler, by Dr. J. M. T. Finney of Baltimore, being a lecture delivered under the auspices of the Osler Memorial Association of Los Angeles.

THE annual dinner of the Hunterian Society will be held on Wednesday, February 8th, at the Trocadero Restaurant, at 7.30 p.m., the President, Mr. Russell Howard, in the chair.

A GENERAL meeting of the Tuberculosis Society will be held at the Margaret Street Hospital, London, W.1, on Monday next, January 23rd, at 7.30 p.m., when the report of a committee on classification will be discussed.

THE fourth annual Overseas Medical Officers' dinner will be held at the Exchange Hotel, Liverpool, on Thursday, February 9th, 1922, at 7.30 p.m. Tickets (price 16s.) may be obtained from the honorary secretary, Dr. G. F. R. Smith, 19, Queen's Drive, Mossley Hill, Liverpool.

THE de Roaldes prize of the American Laryngological Association, a gold medal of the value of 150 dollars offered for the best original thesis upon a subject pertaining to laryngology or rhinology, is now open for competition to non-members of that association. Theses must be in the hands of Dr. D. Bryson Delavan, 40, East 41st Street, New York, U.S.A., Chairman of the Prize Committee, before April 1st, 1922.

A BOY died recently in St. Mark's Hospital, New York, shortly after admission, and on investigation it was found that he had been treated for two days before admission by a "chiropractor." *Post-mortem* examination revealed the fact that death was due to a ruptured appendix, which it was thought might be due to the manipulations the unfortunate boy had undergone. Several "chiropractors" are at present under indictment for murder in the United States on account of other cases of malpractice.

THE entrance standard for students of the Faculty of Medicine at McGill University, Montreal, is to be raised next session; a preliminary standard of one year in arts, senior matriculation, or its equivalent will thereafter be necessary.

THE third South American Infant Welfare Congress will be held this year in Rio de Janeiro.

FOR the past twenty-five years the official monthly magazine of the Medical Mission Auxiliary of the Church Missionary Society has been known as *Mercy and Truth*, but it has now been decided to change its name to *The Mission Hospital*, as a better description of its contents. The first issue of the magazine, which is to appear monthly, was published on January 1st. It is well illustrated, and contains many articles and notes of interest in regard to mission hospitals abroad, including an article by Dr. D. Duncan Main on the work carried on at Hanchow.

THE United States Public Health Service is arranging to send, through the Naval Radio Station at Anacostia, U.S.A., a wireless telephone message every Tuesday and Friday, at 3 p.m., to advise on how the average man and woman may ensure continued good health. It is stated that the messages will be of such a wave length that any radio station, amateur or professional, which possesses a telephonic attachment will be able to hear them, and, according to the *New York Medical Record*, under favourable weather conditions the service expects that its "helpful health hints" will be heard as far as Europe, which we hope will be duly grateful.

TWO representatives of the Medical School of the University of Belgrade, Dr. George Joannovich, professor of pathological anatomy, and Dr. Radenko Stankovich, pro-

fessor of medicine, paid a short visit to London last month as guests of the Rockefeller Foundation. They had previously visited Canada and the United States. In this country they were received by Sir George Newman, chief medical officer to the Ministry of Health, and under the guidance of Dr. R. J. Reece, senior medical officer to the Ministry, they studied the system of control of infectious disease in this country. They visited the medical departments of University College, the Medical Research Council's laboratories, the Lister Institute, the Cancer Research laboratories, and the Bland-Sutton Institute of Pathology at the Middlesex Hospital. They were shown the working of the V.D. clinic at St. Thomas's Hospital by Colonel Harrison and the North-Western Fever Hospital and Ambulance Station by Dr. Goodall; they also paid visits to the Royal Army Medical College, the Wellcome Bureau of Tropical Diseases, and the Museum of the Royal Sanitary Institute.

AT the criminal court of Hamburg, after a trial lasting fifteen days, a manufacturer and his superintendent were sentenced to three and a half years' imprisonment and to five years' disenfranchisement for adulterating salvarsan. Sixteen defendants were sentenced to two years' imprisonment and sixty-two others who had conducted a flourishing business in adulterating salvarsan were fined 20,000 marks.

THREE Canadian universities—Toronto, Western, and Queens—are co-operating with the Ontario Medical Association in a scheme to keep medical practitioners in out-lying districts in touch with recent developments in medicine by means of extension courses. The province has been divided into ten sections, and at a central point in each it has been arranged to hold various courses and give lectures covering a period of six weeks in each year. The courses have already been begun and have proved very popular, many practitioners travelling hundreds of miles to attend them.

A DINNER was held in New York, on November 22nd, in honour of Dr. Virgil P. Gibney, who has been for fifty years surgeon to the Hospital for Ruptured and Crippled Children, New York.

THE National Medical Association of China has issued a directory of Chinese medical graduates; it contains 1,160 names, and gives the year of graduation, qualifications, appointments held, and present address.

THE distribution in France of ninety prizes to the parents of the largest families, under the terms of the Chancelard trust fund, shows that whereas in 1920 only 24,000 families sought awards, in 1921 more than 42,000 entered the competition; several families of eighteen, sixteen, and fifteen children were reported, chiefly from the departments of the south.

UNDER the will of the late Mr. W. C. Reid of Edinburgh, the Edinburgh Royal Infirmary and the Longmore Hospital for Incurables, Edinburgh, each receive £8,000.

THE Royal Society of Archaeology of Brussels has formed a section of the history of medicine, the first meeting of which was held on December 9th. Dr. Mëlis was appointed president, and Dr. Muls, of Brussels, secretary.

THE manufacture, sale, or offering for sale of horsehair shaving brushes has been prohibited in New York owing to the danger of anthrax being contracted through their use.

Up to November 19th, 1921, the total number of cases of plague affecting human beings reported in Queensland was 71; there had been 38 deaths.

MR. W. H. DOLANORE, M.R.C.S., L.D.S., has been elected to a seat on the Board of the Medical Sickness, Annuity and Life Assurance Society, Limited.

A BANQUET was held recently at Havana to celebrate the twenty-fifth anniversary of the *Revista de Medicina y Cirugía*.

THE third annual dinner of the Incorporated Vermin Repression Society will be held at the Trocadero Restaurant, Shaftesbury Avenue, on Wednesday, January 25th, at 7.45 p.m., with the President, Lord Aberconway, in the chair. The chairman of the society is Dr. Nathan Raw, the honorary director Mr. Alfred E. Moore, the honorary secretary Miss E. D. Knight (Brentmead Place, Golders Green, N.W.11).

THE number of volumes collected for the library of the Jewish University at Jerusalem is 40,000. Separate volumes or collections should be sent to the secretary of the University, Dr. D. B. Stanhill, 75, Great Russell Street, W.C.1.

THE official account has just arrived of a Pav Congress of Epidemiology and Bacteriology held in May, 1921; discussions were held on the prophylaxis of plague, cholera, dysentery, male jaundice, encephalitis lethargica, tuberculous scurvy, and trachoma, on the provision of serum, and the control of serums, on disinfection, and press.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Antilegus*, Westrand, London; telephone, 2630, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus*, Dublin; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

"M. W." asks for statistics with regard to the prevalence of progressive muscular atrophy amongst printers.

"PAROXYSM" asks for information regarding the treatment of bronchial asthma by injections of tuberculin, with special reference to dosage, and any untoward effects which have been observed to attend it.

TRAINING OF AN OPHTHALMIC SURGEON.

IN reply to an inquiry recently received we are advised that a practitioner of sixteen years' standing, with a good knowledge of refraction and a fair knowledge of diseases of the eye, would best obtain the experience necessary for taking up ophthalmic work as his sole practice by attaching himself to an ophthalmic hospital or general hospital where there is a post-graduate college—for example, in London he might join Moorfields, the Central London, Royal Eye, or Westminster Ophthalmic Hospitals, the West London Hospital Post-graduate College, or North-East London Post-graduate College (Tottenham). As time is an object and a variety of experience is needed he should arrange to work at one hospital in the mornings and at another in the afternoons. He should aim at joining a hospital where he would be likely to obtain an appointment as clinical assistant at an early date, for he will progress in proportion to the responsibility attached to his work. He should reckon on one year as a minimum time required even in view of his present experience, especially if he desires to obtain some ophthalmic appointment in the region of his future practice; with a shorter period he can scarcely obtain such recommendations from those with whom he has worked as will carry weight with those who have the assignment of ophthalmic posts. He might consider the advisability of working for one of the diplomas in ophthalmology, either that of the University of Oxford or of the Royal College of Surgeons of England.

INCOME TAX.

"HIGHGATE" is a dental surgeon with a medical qualification. He holds an appointment to a home about twelve miles out of London; he is assessed under Schedule E for that remuneration, and the local inspector has refused his claim to an allowance for the expense of travelling to the home in question from his residence.

If the emoluments in question must be assessed under Schedule E the expenses cannot be allowed, as it was held in "Cook v. Knott" that such expenses are incurred not "in the performance of the duties," but to place the person assessed in a position to commence their performance. But medical practitioners holding appointments are permitted to include fees from such appointments with their general receipts for combined assessment under Schedule D, and in those circumstances the whole of the travelling expenses are deducted. Unfortunately this practice is based on concession rather than on right; and our correspondent's circumstances are not quite *pari passu* with the normal case, as he is not in private practice of a nature to necessitate travelling. We suggest that he ask the inspector to arrange for the combined assessment of both his dental and medical practice, but legally cannot demand this or require the all-inclusive expenses.

LETTERS, NOTES, ETC.

PARATHYROID IN THE TREATMENT OF CHILBLAINS.

"H. E. D." writes that he has obtained the most gratifying result in a very severe case of chilblains of long standing, by the administration of parathyroid gland (Armour), 1/20 grain daily. The patient was a boy, aged 15. As "H. E. D." has no opportunity of testing personally the value of the treatment in a large number of cases, he asks medical officers of public schools and physicians of children's hospitals to give the method a trial. He suggests that, in some cases, lime salts should be combined with the parathyroid, and, in others, that the latter be given separately, in order that a firm decision as to the part played by parathyroid may be reached.

THE NAUSEATING EFFECT OF QUININE.

COLONEL G. F. ROWCROFT, M.R.C.S. (U.P., India) writes: I think the medical and chemical professions have been altogether too complacent and self-satisfied with the final form that quinine has been allowed to remain at as a drug. How many tons of this costly product have been wasted! How often has one seen a dose administered and immediately rejected by the unfortunate patient by vomiting! I have been quite uncontrollably guilty of this waste myself, and I write this while convalescing from a severe attack of malaria, before the recollection of the event becomes dim. If a person be only slightly indisposed, even large doses of quinine can be swallowed without much worry or effort, and the taste wears away after half an hour or so, whilst small doses of a grain or two—for example, in ammoniated quinine—are as nothing. (I have met one or two individuals who, when in health, said they liked the taste of quinine.) But, when one feels almost in extremis, quinine is a nauseating and disgusting medicine, a dose of 5 or 10 grains or more often provoking the most violent vomiting, adding greatly to the distress and enfeeblement of the patient, and, in any case, leaving a taste which remains in the month for the whole of the rest of the day. Nothing seems to dispel it. It seems to instantaneously soak into the mucous membrane of the mouth and pharynx (and even nasopharynx after vomiting, some being frequently forced up there), as if that membrane were blotting-paper, and thence it exudes for hours and hours afterwards, even after nourishment is subsequently taken. There are, of course, various "dodges" for disguising the flavour, but none of them amount to much. Surely in the year of grace 1922 our chemists can produce something a good deal less nauseating and more palatable. Let them try (and not leave it to foreign chemists) and they will earn the gratitude of thousands of sufferers and incidentally save many hundreds of pounds.

P.S.—What about the theory of the value of a purgative before the first dose, the explanation given being that, otherwise, quinine and bile form an inert compound? One often continues taking the drug several times a day for several weeks, but if the above theory is true (though nobody denies the value of the purge), how do the later doses exert any therapeutic effect?

THE MOTHER TONGUE.

DR. W. L. STOREY (Belfast) writes: Allow me to express my appreciation of the first leading article in the BRITISH MEDICAL JOURNAL of January 7th. It is good reading and very provocative of thought. "The mother tongue" has unfortunately some descendants which are nothing but bastard English. Our profession is in constant need of the warning, *Cave canem*, the animal to be avoided being not only dog Latin but canine English. What would Addison or Macaulay think of the present-day spelling and colloquial speech, and the style of composition favoured by the newspapers? But, then, would either of those great writers now make his fortune as a leader writer?

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 29, 32, and 33 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 30 and 31.

THE following vacant appointments of certifying factory surgeons are announced: Allendale (Northumberland), Amptill (Bedford), Deal (Kent), Polesworth (Warwick), Ramsbottom (Lancs), and Yaxley (Huntingdon). The appointment at Kingsbridge (Devon) will be vacant in March.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post-restante* letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

51. The Bismuth Treatment of Syphilis.

It seems possible that the treatment of syphilis by salts of bismuth may prove effective. In 1916 SEXTON and RAUDET (*Annales de l'Institut Pasteur*, 1916, xxx, 261) showed that bismuth had a preventive, and up to a certain point a curative action on the syphilosis of poultry and also on trypanosomiasis. In May, 1921, SAZERAC and LEVADITI (*C. R. de l'Acad. des Sciences*, 1921, clxxii, 1391) reported the results of their treatment by the tartro-bismuthate of potassium and sodium of experimentally produced syphilis in rabbits, the spirochaetes being supplied by a dermatropic virus from a case of primary syphilis in man, passed several times through rabbits, and also by a virus from a general paralysis; they also used a virus of the spontaneous spirillosis of the rabbit. When the lesions of the experimentally induced syphilis were fully developed and contained numerous spirochaetes they were treated by hypodermic or intramuscular injections of the bismuth salt. An undoubtedly curative therapeutic action was manifested, they state, not only on the experimental syphilis of the rabbit (the dermatropic and the neurotropic virus), but also on the spontaneous spirillosis (*Spirochaeta cuniculi*). The curative effects on the trypanosomiasis of guinea were less powerful. In syphilis the spirochaetes disappeared in two to four days, and in one case there was no relapse after four months. In August, 1921, SAZERAC and LEVADITI reported (*C. R. de l'Acad. des Sciences*, 1921, clxxiii, 335) further studies on the treatment of five human cases of primary, secondary, and tertiary syphilis by bismuth salts. There was rapid disappearance of the treponemata of open lesions and cicatrization of the latter within a few days; the treatment was successful on primary and secondary syphilitic adenopathies and also in tertiary syphilis. In one case, treated from the onset, the Wassermann reaction, which was positive, became negative and remained so for the two months of the treatment. In the other cases it remained positive. In one there was stomatitis, readily cured by methylene blue, and in another the gums were affected. The writers used intramuscular injections of the bismuth salt suspended in oil, and they advise avoidance of hypodermic and intravenous injections in the treatment of human syphilis. The number of injections varied from six to ten; the total dose during the treatment varied from 1 to 1½ grams. Four other physicians reported to SAZERAC and LEVADITI their favorable results by this treatment in man. In October, 1921, A. MARIE and FOURCADE (*Soc. de Méd. de Paris*, October 22nd, 1921) obtained good results by the tartro-bismuthate of potassium in ten cases of neurotropic syphilis; cases of diffuse syphilitic lesions were more rebellious. In October, 1921, FOURNIER and GUENOT (*C. R. de l'Acad. des Sciences*, 1921, clxxiii, 674) reported their experience of the treatment of 110 cases of human syphilis at various stages by the tartro-bismuthate of potassium and sodium in oily suspension. They confirm the findings of SAZERAC and LEVADITI. The action on the chancre is that the treponemata disappear sometimes after the first injection, generally after the second. Small chancres cicatrize in six or seven days, large ones in twenty. The adenopathy was lessened, the treponemata disappeared from those syphilitic lymph-nodes which were examined, and clinically the course of the disease seemed to be checked; no cases showed any secondary signs. Action on secondary syphilis, they state, is that the treponemata disappear on the surface and in the depth of the lesions; eroding lesions dry up and cicatrize extraordinarily quickly, but papular and hypertrophic lesions rather more slowly. A case of palmar syphilis recovered in fifteen days. General symptoms, such as headache, lassitude, and bone pains, disappeared after the first injection. In five patients who had resisted all treatment (even as many as 700 arsenical or mercurial injections in four years), all the syphilitic lesions vanished after three or four injections of the tartro-bismuthate; but after three months the syphilitic manifestations recurred to some extent. In a case of acute syphilitic meningitis all the symptoms, including the lymphocytosis of the cerebro-spinal fluid, disappeared after three or four injections. In this case bismuth was recovered from the spinal fluid. The action on tertiary syphilis is that bismuth is very efficacious in all sorts of lesions—gummata, osteoperiostitis, and large scabby ulcers of abdomen and thorax. In one case of lingual leucoplasia the lesion diminished con-

siderably without entirely disappearing. The effect on the Wassermann reaction was that in 6 out of 20 cases treated for more than three months the reaction became completely negative. Further study, however, is needed on this head to judge of the depth of the action of bismuth in syphilis. The first results, however, have been very satisfactory. The intramuscular injections of the tartro-bismuthate are given every other day, at the beginning of the treatment, in a dose of 0.20 gram, or every three days in a dose of 0.30 gram. Later the interval is slightly lengthened, especially if stomatitis appears. The total dose given during the first series of injections should reach 2 to 2½ grams in the three or four weeks. The injections are well borne; the only trouble (rather frequent) is a stomatitis, but it is much milder than mercurial stomatitis. It can be prevented by care of the gums and teeth, and by local application of the bismuth salt, methylene blue, or arsenical compounds. The writers recovered bismuth from the blood, urine, saliva, bile, and faeces; sometimes there was slight polyuria and albuminuria. Their general conclusion is that bismuth must be regarded as an energetic antisiphilitic agent. Prolonged and numerous observations are, however, needed to show whether it can definitely cure syphilis. Not only has it a rapid and a lasting effect on all sorts of syphilitic lesions, but it has great value from a social point of view, for it acts on the contagiousness of syphilitic lesions. The researches of SAZERAC and LEVADITI may possibly thus prove to have found a new therapeutic weapon against syphilis: certain bismuth derivatives tried by these writers were found to be much more toxic than the tartro-bismuthate salts.

52. Mercury and Bismuth.

MILIAN (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, November 17th, 1921) remarks that though absolute intolerance for mercury is rare, all gradations may be found between perfect tolerance and absolute intolerance, and that many persons suffer in some degree from mercurial medication. Some patients are unable to take mercurial pills for more than a fortnight at a time, and others have more or less acute attacks of enteritis with or without haemorrhage after injections of cyanide of mercury. During the last ten months Milian has been using subnitrate of bismuth in cachets combined with calomel when mercury is given by mouth. In the case of intravenous or intramuscular injections he orders a cachet of 1 gram of subnitrate of bismuth daily. In this way stomatitis and gastric and intestinal disturbances are prevented.

53. A Mixed Diet in the First Year of Life.

JUNDELL (*Acta Paediatrica*, vol. i, fasc. 2, 1921) challenges the orthodox view that infants under 12 months should not be given a mixed diet. Since 1914 he has given a mixed diet in the second half of the first year to infants in an orphan asylum in Stockholm, and of the 2,185 children under one year, 382 were given a mixed diet including porridge, gruel, tea with milk, beef-tea, fruit-juice, soups, cocoa, scrambled eggs, minced meat and fish, rusks, mashed potatoes and vegetables, and stewed fruit. Between 300 and 550 c. cm. of milk were given daily, and the infants were allowed to eat as much as they liked of the above dishes. The author publishes numerous tables showing the effects of this dietary, and he claims that, on the whole, the results were satisfactory, and in a certain number of cases this mixed feeding proved of the greatest value. He concludes that there is no risk in giving a mixed diet to an infant after the age of nine months, and that such feeding may, in certain cases, have a very favourable effect on the infant's health and development.

54. Treatment of Anaphylactic Symptoms of Allimentary Origin.

CLARET (*Bull. Soc. de Théor.*, October 12th, 1921) states that after unsuccessful treatment of this condition by various drugs he has given hexamethylene tetramine by mouth with success, being guided by the following considerations: (1) The drug raises the blood pressure and increases its viscosity; these conditions, as LUMIÈRE has shown, tending to inhibit the development of anaphylaxis. (2) Insufficiency of the liver and kidneys, on which this drug has a selective action, creates a condition favourable for the development of anaphylaxis. Rapid recovery followed administration of uroformine in doses of 1 to 1½ grams daily.

55. **Erythema Nodosum.**

GUEISSAZ (*Rev. méd. Suisse rom.*, October and November, 1921) discusses the following theories as to the etiology of erythema nodosum, which was first described by Willan. (1) The oldest view, that it is a rheumatic manifestation, was maintained by Barthez (1802), Schönlein (1829), and Bonillaud (1840), this theory being founded on the presence of pains in the joints which are almost constant. (2) Writers such as Cruveilhier, Chomel, Tardieu, Griscelle, Trousseau and Germain Sée contest its rheumatic origin, and maintain that it is an independent infectious disease. (3) During the last fifteen years almost all writers have been inclined to regard erythema nodosum as closely connected with tuberculosis. Thus Voyer in 1920, out of 47 cases of erythema nodosum, found in 46 either a tuberculous heredity or stigmata of tuberculosis in the patient. According to Gueissaz erythema nodosum is not a frequent disease. At the Lausanne Polyclinic only one case was found among 1,000 cases of all kinds. The disease is most frequent in the north, especially in Scandinavia. At Hamburg the average number of cases is also 1 in 1,000 (Hegler). According to Schultbess at the Zurich Polyclinic, out of 80,000 patients, there were 113 of erythema nodosum, or 1.4 per 1,000. Gueissaz found that country folk were almost as frequently attacked as townspeople. Three times as many girls as boys were attacked in his statistics, as in Syme's (vide *BRITISH MEDICAL JOURNAL*, April 25th, 1914). In six of Gueissaz's cases several members of the family were attacked. Usually the weaker children were affected, but after the age of 15 the disease was equally frequent among those with a good constitution. Gueissaz's conclusions are as follows: (1) There is a primary specific erythema nodosum which possesses all the characteristic features of an acute exanthema. The proofs of its autonomy are as follows: (a) The disease attacks females more frequently than males; it occurs at every age, but is commonest between 5 and 20; it is a definitely seasonal disorder, being most frequent in spring; it attacks all classes of society both in the country and in the town. (b) Erythema nodosum is an undoubtedly contagious disease, the pathogenic agent of which is still unknown, but has sometimes its portal of entry in the tonsils. It may occur in epidemic form. (c) Erythema nodosum conveys immunity, instances of a second attack being extremely rare; it may develop in persons free from any other infection, but it attacks quite as frequently the tuberculous or rheumatic. (2) Under certain conditions tuberculosis, syphilis, malaria or leprosy may give rise to an eruption resembling erythema nodosum. In tuberculosis in particular a relapsing erythema may occur which at its onset presents the features of erythema nodosum, and in its repeated attacks resembles the erythema induratum of Bazin.

53. **Quinidine in Auricular Fibrillation.**

WOLFFERTH (*Amer. Journ. Med. Sciences*, December, 1921), from an experience of twelve cases of auricular fibrillation treated with quinidine sulphate, considers the most favourable cases to be those with relatively good heart muscle and fair compensation, and those in whom the condition has existed for only a short time. Normal rhythm was restored in seven, fibrillation was converted to flutter in one, and in four the treatment failed. Of other reported cases quinidine restored normal rhythm in slightly over one-half. On account of the possibility of hypersusceptibility to the drug one or two small doses (0.2 gram) should be given as a preliminary, increasing from 0.4 gram to 1 gram three times a day if no such hypersusceptibility is present. As soon as normal rhythm is obtained the large doses should be reduced to such smaller dose—for example, 0.2 gram twice a day—as is found best to maintain the improvement, and after a period of ten days the drug should be discontinued for a few days, and a second course instituted if the condition returns. The co-existence of valvular disease does not contraindicate treatment and in no case were serious effects noted, though in four of the cases increasing weakness, dyspnoea, dizziness and precordial distress, and symptoms of euclonism, necessitated withdrawal of the drug. In three cases a sudden increase in the ventricular rate occurred, and in such cases it was found to be desirable to continue the drug when it was already exerting a beneficial effect upon the fibrillation, only withdrawing it in the presence of cardiac embarrassment, or when the tachycardia developed before the fibrillation had been altered.

57. **Bromide Delirium.**

KARPMAN (*State Hosp. Quarterly*, November, 1921) suggests that the continued use of bromide, by lowering resistance, produces a definite intoxication manifested by physical and mental disturbances. Emaciation and weakness; acneiform eruptions, ulcerations and gangrene; constipation, anorexia, foul breath and furred tongue; ataxia, exaggerated knee-

jerk, tremors and dilated pupils are among the physical disturbances; while on the mental side there are hallucinations and alternations of excitement and stupefaction. Depression is the chief effect of bromides upon the brain, and, through the primary alteration in metabolism and progressive intoxication, a toxæmia is produced, which is essentially the same whether it is produced by infection, drugs, or exhaustion.

SURGERY.

58. **Vaccines in Osteomyelitis.**

HALLOPEAU (*Bull. et Mém. Soc. de Chir. de Paris*, December 13th, 1921) discusses the value of vaccine treatment in cases of acute osteomyelitis. He advises that injections should be given at intervals of eight days, and not every two days as has been suggested. In those cases where the vaccine treatment has been carried on over several months their value is doubtful. As a result of his experience in a number of cases, he considers that in only a few patients did the vaccine have any effect on the resolution of the condition. The relief of pain and symptoms has been such as could be brought about with routine treatment. In a few cases suppuration was arrested by the vaccine, but he considers this to be an exceptional occurrence. It is not justifiable to delay operative treatment, but vaccines should be combined with this, as they are free from danger. Further, by delay in operating there is a risk that the necrosis of bone may be more extensive when there is a collection of pus surrounding the bone. Though vaccine treatment cannot prevent the necrosis of bone, it does in some cases bring about the reabsorption of pus in a localized abscess and hasten the recovery. Vaccines are of little use in treating old sinuses.

59. **Osteomyelitis of the Patella.**

ACCORDING to A. MOUCHET (*Bull. et Mém. Soc. de Chir. de Paris*, November 29th, 1921), who communicates a case reported by Duguet in a soldier following typical influenza bronchopneumonia, in which recovery followed removal of the patella, osteomyelitis of the patella is a rare condition, only 18 cases, including the present one, being on record. Sometimes it develops spontaneously, either in a chronic form from the first (Berger) or in an acute form (Walther), either without apparent cause (Ropke, D'Ollier) or following a previous infection, such as small-pox (Poncet), septic puncture of the finger (Wood), bronchopneumonia (Duguet), or anthrax (Parsch). As regards the functional result after removal of the patella, flexion is limited to 45 degrees, but extension is complete.

60. **Haemorrhagic Osteomyelitis.**

ARNOLD (*Boston Med. and Surg. Journ.*, December 15th, 1921) calls attention to a rather infrequent bone lesion which is apt to be mistaken for tuberculosis or new growth. The condition—one of haemorrhagic osteomyelitis—occurs almost exclusively in childhood, and appears to be of the nature of reaction to trauma. Macroscopically, a unilocular cavity is found in the spongy bone, filled with a dark brownish mass of jelly-like consistence from which uncoagulated blood oozes. A brownish-red membrane, about an eighth of an inch in thickness and very friable, lines the wall. The whole bone shows a uniform expansion. Microscopically, the mass is seen to be a haemorrhagic extravasation containing young fibroblastic tissue and numerous multinucleated giant cells. The symptoms are purely local, so that the disease may only be revealed by the x-rays, which show a regular, sharply outlined cavity with absence of bone proliferation. Treatment consists in evacuation of the contents of the cavity, complete curettage of the haemorrhagic membrane, and suture of the periosteum and skin without drainage.

61. **Tendon Transplantation.**

POATE (*Med. Journ. Australia*, October 1st, 1921) discusses tendon transplantation in old nerve injuries where nerve suture is either impossible or has failed, the sole object being to restore function by reconstructing or improving the muscular balance of the region affected. Each case must be considered on its merits as to which tendons require assistance, and whence that assistance will be best obtained. It is an essential preliminary that all deformities and contractures should be corrected, and that all joints involved are freely mobile. The direction of the transferred or active tendon should be as near as possible to that of the receiving or paralysed one, and in order to avoid loss of power tendons should not be carried round in a sharp bend. Substitution of small muscles for large ones is undesirable, and, in selecting muscles for transplantation, an amount of muscle substance in the transferred muscle equal to that of the paralysed one

should be aimed at. It is preferable, in bringing a tendon to its new position, that it should pass through the subcutaneous and fatty tissue rather than through the deeper tissues, as better nutrition and less liability to adhesions are likely to result. One tendon can only be made to subserve one function, and it is useless endeavouring, by splitting tendons, to expect the various parts to take on independent function. Tendon to tendon implantation is usual, though in some situations periosteal insertion is possible. Incisions should be planned to allow free manipulation, but so that the resulting scar is not directly over the transplanted tendon. By maintaining the limb fixed in the corrected position for six to eight weeks, with gentle passive movements after a few days, the patient usually obtains full control in from eight to ten weeks, requiring no further treatment after three months.

62. Cutaneous Leishmaniasis.

ACCORDING TO CALICETI (*L'oto-Rhino-Laryngologie Internationale*, December, 1920), excellent results may be obtained in leishmaniasis of the nose and ear by local injections of emetine hydrochloride, which are superior to intravenous injections. He records two cases in which the nostril and the auricular pinna respectively had been affected for about six months. Three weeks after two successive injections of 8 to 10 eg. of emetine hydrochloride into the base and periphery of the swelling cure was attained. Diagnosis was established eventually by the finding of the *Leishman* bodies in the serum from the sores; in one case the first examinations were negative, but the blood serum was found to contain the antibodies described by Pavoni. The deviation of the complement due to these bodies was shown with antigen extracted from the spleen of patients dead of internal leishmaniasis, but was absent when the antigen used in the Wassermann test were employed. Caliceti attributes great importance to this complement deviation test in early diagnosis of leishmaniasis. These two cases of oriental sore occurred in Sicily, where leishmaniasis, both internal and external, is endemic.

63. Methyl Violet in Suppurating Wounds.

FOR some years ASER (*Tidsskrift for Den Norske Lægeforening*, October 1st, 1921) has been experimenting with methyl violet (pyocetanninum coeruleum medicinale) in suppurating wounds and such skin conditions as impetigo contagiosa. His verdict is favourable. His success with several cases of impetigo contagiosa was all the more striking as the disease had proved refractory to other antiseptics. The remedy did not fail in a single case, and it was common to find the lesions healing in a couple of days. One of the author's patients was a man on whom an operation had been performed for hypertrophy of the prostate. The abdominal wound failed to close and there was profuse discharge of pus from the fistula. The tissues about the fistula were brawny, and the pus showed signs of burrowing under the skin. Various ointments and compresses had been tried and dilatation of the fistula had been performed, but no improvement occurred till the wound was carefully painted with a 0.1 per cent. aqueous solution of methyl violet and then covered by a pad of cotton-wool soaked in the same solution. This treatment was repeated twice a day, and after a week marked improvement was observed. A fortnight after the institution of this treatment the discharge had ceased and the wound closed. The author has found methyl violet remarkably effective in the treatment of gonorrhoea in the male, and he considers that when as weak a solution as 0.1 per cent. is used, the drug is neither painful nor dangerous.

64. The Development of Tumours in Children.

DE BRUIN (*Nederl. Tijdschr. v. Geneesk.*, November 12th, 1921) states that out of 4,758 children treated in the surgical department of Professor Rotgans at Amsterdam from 1901 to 1920, 62, or 1.3 per cent., presented tumours of some kind, as compared with 24, or 0.54 per cent., of the 4,447 children treated by himself in the medical department of the same hospital, and 1,591, or 7.32 per cent., out of 20,356 adults treated by Professor Rotgans during the same period. In other words, tumours were five times more frequent in the children's surgical department and fourteen times more frequent in the adult surgical patients than in the children's medical department. As regards the character of the tumours, growths consisting of connective tissue elements, such as fibromata, lipomata, chondromata, osteomata, and angiomas, were more frequent in children than epithelial tumours. The benign epithelial tumours which occurred with relative frequency in children were papillomata of the skin and larynx and polypi of the rectum, no less than 9 of the 24 cases in the medical department showing rectal polypi. Sarcomata were much more frequent in children than carcinomata, as is shown by the fact that during the period 1901 to

1920 no case of carcinoma was seen in either the medical or the surgical department of the hospital, as compared with 14 cases of sarcoma in the surgical department and 10 in the medical department during the same period. On the other hand, certain tumours were more frequent in children than in adults. Thus during the period mentioned, in Professor Rotgans's clinic 19 cases of rectal polypi occurred in children and only 11 among five times as large a number of adult patients. Similarly, only 3 cases of renal sarcoma occurred during the same period among adults and 4 in children. As regards the difference in the effects of the tumour on the organism of adults and children, the disease runs a much quicker course in the latter, so that death from exhaustion or intercurrent pneumonia occurs before cachexia has had time to develop.

65. Powdered Yeast in the Prophylaxis of Sore Throat.

FRIZ (*Deut. med. Woch.*, October 20th, 1921) started his investigations with the familiar knowledge that the introduction of yeast into septic cavities in the body may, by its growth, inhibit the activities of bacteria. This principle has been applied to the treatment of diphtheria by Gallion, but not with very good results. The author is much impressed by the practical value of this idea in other forms of sore throat, and he has succeeded both on himself and other persons in aborting attacks of acute pharyngitis by blowing powdered yeast into the throat. In his own case he had been subject since childhood to attacks of acute sore throat, which recurred at some seasons as often as every four to six weeks and rendered him unfit for work for a day or two each time. Local applications and incisions of the small but much eroded tonsils had proved futile, and gargling with astringents and disinfectants had only occasionally aborted the disease in an early stage. He was greatly surprised when he found the insufflation of yeast invariably aborted the disease, the first manifestation of which was slight dysphagia. The same success was achieved in every adult and most of the children on whom he tried this remedy, which is, in the author's opinion, perfectly harmless. The best time for the insufflation is in the evening, just before the patient goes to sleep. With the help of a mirror the patient can apply the treatment himself.

OBSTETRICS AND GYNAECOLOGY.

66. The Frequency of Malignant Metastasis in Myoma.

ACCORDING TO BERREITTER (*Zentralbl. f. Gynäk.*, November 5th, 1921), in view of the now frequent treatment of myoma by radiation or radium in preference to operation, it has become of importance to assess the frequency with which myomata undergo malignant metastasis. The figures given in the literature vary widely: Borée found 1.7 per cent. of cases in a series of 1,400, and Noble and also Lewis give similar findings. Schöckländer found 5.9 per cent. of cases of malignancy in a series of 3,160, and Mackenrodt pronounced a percentage of 6 or 7 per cent. to be too small. Berreitter believes, on the other hand, that the last-named percentages are much too large; the high degree of frequency of sarcoma reported by many authors is due to the difficulties which beset the histological examination of the tumours, to many cases having been regarded as malignant from clinical findings not tested microscopically, and, lastly, to the tendency which has been shown to base a diagnosis of malignancy upon the reaction to radiotherapy. The author calculates that not more than 0.5 per cent. of myomata are malignant. He ascribes great importance in microscopic diagnosis to the occurrence of numerous irregular giant cells: these were present in each of the six cases of malignant metastasis which he was able to detect among a series of 716 myomata which were subjected to systematic histological observation.

67. Interposition Combined with Supravaginal Hysterectomy for Prolapsed Uterus.

VINEBERG (*Amer. Journ. of Obstet. and Gynec.*, October, 1921) remarks that in operating for prolapsed uterus and cystocele it is often impossible to interpose between the bladder and the vaginal wall a uterus which, on account of the presence of single or multiple fibroids, is enlarged beyond the size of the gravid organ at the eighth week. In certain cases also of so-called idiopathic metrorrhagia it may be inadvisable to retain the uterus. For the first-named cases the surgical procedure usually adopted has been (1) preliminary excision of a wedge-shaped area from the fundus or anterior uterine wall, but subsequent primary union of the thickened uterine wall is rarely obtained; (2) total hysterectomy, with suturing of the round ligaments (Goffe's operation); or of the broad ligaments (Mayo's operation); or (3) as a measure preceding

the plastic operation; amputation of the corpus uteri at or above the level of the internal os; subsequently the cervical stump is utilized as a *pelotte* to hold up the bladder. The third procedure is due to Löwit. Vinberg modified it by suturing the cervical stump to the subpubic ligament and by adding to the operation an amputation of the vaginal portion of the cervix when it is markedly elongated or diseased. After separation of the bladder and delivery of the corpus uteri through the vaginal incision (the vesico-uterine fold having been incised) the broad ligaments are sutured and divided, the uterine arteries are ligatured, and the corpus uteri is amputated. The cervical stump is now fixed to the subpubic ligament by means of a catgut suture, which passes through the subpubic fascia underneath the vaginal mucosa, transfixes the cervical stump from behind forwards, and is then carried through the subpubic fascia in the opposite direction; firm union is secured of the stump with the raw tissues beneath the pubic arch and thus firm support is given to the bladder. In a series of 30 cases treated by this method there has been one failure and one recurrence.

68. Abdominal Hysterectomy before Removal of the Cancerous Rectum.

RICHARD (*Thèse de Lyon*, 1921, and *La Gynéc.*, July, 1921) records the late results obtained in thirteen cases treated by Tixier by total abdominal hysterectomy as a preliminary to the operation on the rectum. Six patients have survived more than three years, of whom two have lived for six years and one for more than fifteen years after the operation. The advantages claimed for the preliminary hysterectomy, followed in many cases by removal of the recto-vaginal septum, are the clear view of intrapelvic conditions which is obtained, the possibility in cases permitting conservation of the sphincter of securing sufficient room for conveniently making an end-to-end anastomosis after enterectomy, and finally the possibility at the end of the operation of covering the whole of the field of operation by means of a peritoneal flap brought from before backwards.

69. Diphtheritic Gangrene of the Vagina.

KÜHN (*Zentralbl. f. Gynäk.*, October 29th, 1921) records the case of a patient admitted to hospital for double adnexal inflammation, who underwent an attack of pharyngeal diphtheria, the diagnosis being confirmed microscopically. A few days later acute gangrenous vaginitis occurred, and death followed on the tenth day, a slough comprising the whole of the vagina and the adjacent portions of the rectum and bladder having been completely separated and discharged. Microscopical examination of the slough showed the presence of numerous staphylococci and streptococci towards the mucous aspect, and of bacilli resembling the Klebs-Loeffler organism in the deeper layers. According to the author no case has hitherto been recorded of vaginal gangrene associated with the presence of diphtheria bacilli, or of bacteriologically proved diphtheria associated with vaginal gangrene.

PATHOLOGY.

70. Glomerular Haemangiectases in the Nephritis of Typhoid Fever.

DURING the war SABRAZÈS, BONNIN, and CHANDRON (*C. R. Soc. Biologie*, December 10th, 1921) had occasion to observe an epidemic of malignant typhoid fever in a collection of labourers from Annam. In the numerous cases which came to autopsy they were able to satisfy themselves of the frequency of renal complications. Microscopic examination of the kidneys removed showed the usual features of an acute typhoid nephritis, such as the presence of albuminous exudates in Bowman's capsule, desquamation of the cellular lining of the capsule, cytotoxicity of the epithelium of the convoluted tubules, relative integrity of the cellular elements of the straight tubules, various types of cylindrical casts, collections of small lymphocytes in the interstitial tissue, and small interstitial haemorrhages. In one case, however, which showed during life the extraordinarily high figure for blood urea of 1,000 mg. per 100 c.c.m., a curious affection of the glomeruli was found in the shape of large haemangiectases which either occupied the glomerulus itself or projected in a polypoid manner from one of the capillaries into the intracapsular space. In size they measured from 40 to 60 μ ; they contained red corpuscles, and were lined by a more or less desquamated endothelium situated on a thin border of collagen. From military aneurysms they differed in their failure to show any trace of fibrinous stratification, any thickening of the wall, or anything but a suspicion of endarteritis. Moreover, the absence of blood cells

and clot served to distinguish them from the haemorrhagic cysts met with in experimental diphtheritic nephritis. They conclude by asking whether this lesion is one peculiar to typhoid or whether it may be encountered in other types of nephritis.

71. Composition of the Urine.

AN elaborate investigation into the composition of the urine passed by a healthy individual under various conditions of rest and activity has been made by CAMPBELL and WEBSTER (*Biochem. Journ.*, vol. xv, No. 5, 1921). Investigations were carried on over a period of six months, during which the subject continued on a normal diet. Under all conditions it was found that the total nitrogen of the urine was decreased at night, whereas ammonia excretion was increased at night. Urea, uric acid, creatinine, and amino-acids were excreted in greater quantities during the day. These observers substantiated the fact that the acidity of the urine is distinctly higher during the night and attribute the increased nocturnal excretion of phosphates to the same cause. This has an interesting bearing on one of the well-known theories of sleep, which postulates that sleep is due to an accumulation of acid products in cells, these acids being excreted more slowly than they are formed during the day and thus collecting in the cells, with a resulting diminution of the activity of the cells, particularly of the brain cortex. The authors suggest that the cells of the body may not excrete certain fixed acids into the blood until certain amounts are formed in each cell. When this is the case these acids are excreted into the blood and fatigue or sleep is produced. With reference to the effect of food it was found that the urine was more acid just after a meal, possibly due to removal of alkaline phosphates in saliva, and less acid about two or three hours after a meal, probably due to removal of HCl in gastric secretion. The so-called alkaline tide is thus dependent on digestion.

72. Pathogenicity of Cholera.

SANARELLI (*Ann. de l'Institut Pasteur*, November, 1921) discusses the subject of intestinal cholera in young animals. Although it has been shown that newly-born rabbits can be infected with cholera when administered by the mouth, yet the disease from which they suffer is not a true cholera but an ordinary bacterial colitis. The organisms are absorbed by the mouth and reach the circulation, and are excreted by the intestines. The high acidity of the stomach destroys any vibrios which might be swallowed; the stomach and duodenum are always sterile. Exactly the same picture may be reproduced by injecting the organisms under the skin or into the peritoneum. In the same way cholera vibrios administered by the mouth to rabbits more than ten days old are absorbed by way of the lymphatics into the general circulation. They can be found about twelve hours later in the intestinal canal at the level of the ileum and in the caecum and appendix. Later they ascend a little in the small intestine, but never reach the duodenum. The reason of the resistance of older rabbits to the enterocolitis of cholera is due principally to a diminished permeability for the vibrios of the buccal mucous membrane, and to a less delicate sensibility of the intestinal mucous membrane by which they are excreted. The conclusion to which Sanarelli has been led by these and other researches is that the cholera vibrios can only develop their pathogenic action on the intestines when they reach it by the "reverse direction"—that is, by the excretion from the circulation.

73. Adeno-fibroma of the Breast showing Malignant Evolution.

DURANTE and BOULLAND (*La Gynéc.*, June, 1921) give a full report of a case of adeno-fibroma of the breast with malignant changes. Dividing the epithelial lining of the acini into internal and external layers, they describe the case as one of typical adenoma of the former and atypical carcinoma of the latter. The tumour, which was removed from a woman aged 42, showed fibromatous and adenomatous areas containing one very large and many very small cysts. The small cysts are described as (1) simple cysts regularly lined by cylindrical epithelium showing intracanalicular papillae arising from proliferation of the internal epithelial layer; (2) cysts lined by wider, less elongated cells with more abundant, more feebly staining cytoplasm; these cells showed proliferation, which in many areas led to passage beyond the basement membrane and to formation of a syncytium; (3) a few cysts lined by eosinophile epithelial cells; these cysts are regarded as derived from incisions of sudoriferous glands. The whole of the tumour showed round-celled infiltrative changes, possibly attributable to iatrogenic infection. In this tumour the authors see the simultaneous existence of (1) adenomatous modification of the cells forming the internal lining of the gland acini, and (2) carcinomatous alteration of the cells forming the external layer; both changes are probably to be regarded as a response to irritative infiltration.

An Address

ON

TUBERCULOSIS OF THE LYMPHATIC SYSTEM.

BY

PROFESSOR SIR ROBERT PHILIP, M.D., LL.D.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH;
CORRESPONDING MEMBER OF THE ACADEMIE DE MEDECINE, PARIS;
PRESIDENT OF THE MEDICO-CHIRURGICAL SOCIETY.

No more fitting subject could have been selected with which to commence the activities of the Tuberculosis Society than that which has been proposed for discussion. The significance of the part played by the lymphatic system in the spread of tuberculosis throughout the body seems inadequately recognized in current medical practice and teaching. The subject calls for illumination.

Within the past hundred years medical vision has been progressively clarified regarding the main facts of tuberculosis in remarkable degree. Fundamental positions have been successively determined with precision. First came the clearing of the air, from the morphological point of view, through the convincing teaching of Laënnec as to the unity of tubercle in all its forms. Second, from the biological side, there followed the definite proof by Koch of the essential causal factor.

With these positions determined, advances have been made along numerous lines, both pathological and clinical. The morbid anatomy—macroscopic and microscopic—of tubercle, as it occurs in any organ, has been studied with great exactness. While lacunae exist here and there, our knowledge in this direction is almost complete. From the biological side the life-history of the tubercle bacillus has been followed by pulsed observers. Thereby much has been attained in explanation of its morbid action and in the suggestion and elaboration of methods of treatment and prevention. There has been a gradual evolution of thought regarding tuberculosis whereby the horizon has been widened and faulty perspective has been corrected.

Just Perspective.

The local manifestation of tuberculosis in any one organ, important as it is, is seen to be of relatively less significance compared with the larger fact—of which the local lesion is but part expression—that invasion of the system by tuberculosis has been effected.

Granted successful invasion and live bacilli within the body, the potential of manifestation is infinitely various, both focally and systematically. In no two cases is the pathological and clinical picture identical. In the same case kaleidoscopic effects occur from week to week, and month to month, and year to year. After many years of work in relation to tubercle, my experience is that hardly a day passes without some new point of interest or fresh illustration in one or other direction.

We are gradually getting to the vantage position in respect of tuberculosis which we have for long occupied regarding other chronic infective processes, such as syphilis and leprosy.

Continuous Observation.

This advance has been largely contributed to by prolonged continuous observation of individual cases—not for weeks or months only, but through many years—from the earliest manifestation, for example, in an isolated gland, to successive further developments throughout the subject's life. I have in this manner followed numerous patients from early childhood to manhood or from early adolescence throughout adult life. The line of study is tedious and difficult, but throws a flood of light—not otherwise available—on the natural history of tuberculosis as a whole and particularly on that aspect of the subject which we are now considering. I commend the method of observation to younger workers, who presumably have the potential of carrying it out for sufficient periods.

Facts observed clinically in this extensive fashion are illuminated by comparison with observations in inoculated animals, where the gradually advancing involvement may be more rapidly followed stage by stage from the initial changes at the point of inoculation through successive structures and viscera.

Stages of Infection.

In offering a constructive representation of our present knowledge of the spread of tuberculosis in the human subject certain landmarks may be specially signalized.

Let us admit that the point of inoculation with the tubercle bacillus may be almost anywhere in skin or mucous surface. Opportunities for inoculation are numerous, obscure, recurrent, and notably conditioned by the subject's environment. Dates of exposure to tuberculous infection are less exactly determinable than in syphilis. Nor is the fact of successful invasion by the tubercle bacillus commonly registered in the human subject, as it is in the guinea-pig, by a local sore analogous to the primary sore in syphilis.

Primary Incubation and Initial Local Lesion.

None the less, from the occasional occurrence of demonstrable cases of local sore either of skin or mucous membrane with a definite history of precedent trauma—for example, in laboratory, post-mortem room, or slaughter-house—we are in a position to predicate a measurable period of primary incubation between the actual entrance of the bacillus and the occurrence of the initial local lesion. Whether or not the point of entrance is indicated by the occurrence of an evident local lesion, such point of entrance must be definitely predicated. Much confusion has been introduced into the consideration of the subject, as it seems to me, by the sharp, even acrimonious, difference of opinion which has emerged between supporters of the theory of introduction by inhalation, and of introduction by ingestion. Observers have come to be ranged as if in opposing camps, while the truth would seem to be that both are right.

The outcome of collective observation appears to be that inoculation of the human subject by the tubercle bacillus occurs by varying channels in different cases. While, if entrance occurs through the skin, the event is commonly registered by a definite sore, an obvious lesion is seldom traceable when inoculation has been effected by way of the mucous membrane, as may be the case at any point in the alimentary tract from the lips to the anal orifice, or in the respiratory tract from the nostril to the ultimate alveolus.

The absence of local lesion is likely when infection occurs, as it oftener does, during the tender period of developing childhood. At that date the mucous surfaces are rapidly absorbent and succulent, and the entrance of the tubercle bacilli may leave little, if any, trace. Theoretically, especially at that age, the possibility of entrance at any point of the mucous surface must be admitted, but the greater vulnerability of certain points, notably the tonsillar region, including the posterior nares and fauces, will be kept in view.

Second Incubation Period: Involvement of Lymphatic Glands.

Following successful invasion, whether evidenced by local sore or not, ascertained facts allow us to predicate the occurrence of what may be termed the second incubation period, during which gradual spread by way of the lymph stream is taking place. In the experimental animal the completion of this secondary incubation is evidenced by enlargement of a lymph gland in the vicinity of the initial sore, followed by further extension to other glands.

Careful observation in the human subject, particularly in children, frequently reveals more or less clearly a similar succession of events. Thus, following inoculation of the tonsillar region, one or two external glands may be found evidently enlarged, and then others progressively until, it may be, a network of such enlarged glands in the submaxillary and supraclavicular regions is determinable.

Specially noteworthy in many cases is the fine multiple enlargement of lymph nodes extending in fanlike fashion from the angle of the jaw downwards. The enlarged glands may vary much in size. Such infiltrated and indurated glands may show little tendency to caseation or softening. Indeed, the enlargement is, for the most part, so slight as commonly to be passed over, unless the point is deliberately investigated by specially detailed palpation over likely regions. So far as these glands are concerned, this is all that may happen. To local incidents—or accidents—in the course of the tuberculous involvement I shall return shortly.

Further extension of infection throughout the system proceeds insidiously by way of the lymph stream—legitimate or irregular—until presently, as is readily followed in the experimental animal, groups of glands at a greater and greater distance become implicated, the individual glands undergoing changes similar to those just indicated.

* Introductory to a Discussion on the subject at the Tuberculosis Society of Scotland, November, 1921.

Clinically the evidence of this progressive involvement varies according to the position of the glands and merits observation. In all cases the conditions of more accessible glands—for example, axillary, bronchial, abdominal—should be investigated. Such inquiry frequently yields most important evidence.

As we have seen, the commonly occurring change in the affected glands is infiltration and induration. For the most part there is little obvious disturbance of grosser sort. In this fashion infection spreads quietly from point to point. The glandular changes are so slight as readily to escape notice.

Incidents in Glandular Spread.

Gross enlargement with caseation, with all the possible inconveniences which may follow, is a relatively uncommon event. Such obvious involvement, causing deformity of outline and calling for operative interference on that account, or because of softening and risk of rupture, may be regarded as an uncommon incident compared with the frequency of slight, progressive implication of glands, one group after another, without more striking development.

The deforming swelling or threatened rupture naturally arrests attention. The question of immediate interference requires consideration. There is, however, a serious risk that treatment may be restricted to the obvious disturbance, to the exclusion of the more significant distribution of the disease. There is too little consideration of the steady passage of tuberculous infection in the quieter fashion that has been described. In presence of gross enlargement of glands a thorough-going search should be undertaken for less obvious infiltration which extends frequently over wide areas throughout the body.

Systematic Examination of Lymphatic Glands.

Whether or not immediate local interference is required—for example, with a view to immediate removal of gross deformity, such as a large mass in a pretty girl, or for the discharge of softened caseous material when rupture is threatened—the wider issues of the case must be carefully appraised and handled.

Were this line followed the guidance afforded by early illness would not be lost. It would cease to be common experience to have case after case come under observation for advanced disease with a history of two, four, six, even twelve, successive operations for enlarged glands, or to encounter as great a number of discharging sinuses without indication of effective attempt to deal with the larger question.

Sphere of Vaccine Therapy.

From long-continued observations in a great variety of cases I am satisfied that this is the moment to institute sufficiently prolonged vaccine therapy. The effect of tuberculin, maintained for long periods, is remarkable (1) on the glands which for the moment are more immediately in evidence, (2) on groups of glands less obviously affected, which may be discovered in other areas, and (3) on the intoxication, which is more or less determinable in most instances.

Under the continued use of tuberculin—whether subcutaneously or percutaneously (by innunction), as I have practised with excellent results for many years—the grosser tumours gradually melt away. The agglomerate mass separates into discrete glands, which in turn become smaller and smaller until all that remains, in most instances, is a firm, apparently fibrous core, possibly calcified in part. *Pari passu*, the glands at a distance are influenced, and the advance of disintoxication is registered by the improved appearance of the patient, increase of weight, and recovery of muscular tone.

Further Spread of Infection.

If the lymphatic system has been widely invaded and the advance unchecked, the possibilities of extension to individual viscera and generally throughout the body become almost unlimited, in the absence of arrest of infection. The tubercle bacillus readily passes elsewhere by a variety of channels.

Let me accentuate the point that these channels may be what we may term legitimate, or they may be less regular. In presence of large masses of agglomerated glands—for example, about the neck—there is often conspicuous stasis, and even reversal, of lymph flow. The resultant is the production of the full, heavy, porcine or scrofulous aspect, to which older observers paid much attention. From many

observations following the special lines of treatment indicated, it seems to me that the classic scrofulous appearance is to be explained largely in the way suggested. Under treatment, the gross enlargement becomes sensibly reduced and the glands pass into discrete glands, lymph stasis is removed, and the natural outlines of face and neck are restored.

Among most civilized peoples the stage of glandular involvement—whether as the more commonly occurring fine, multiple implication, or the grosser enlargement associated with deformity and softening—is chiefly determinable in children, occurring more rarely at later ages. Among uncivilized peoples, on the other hand, this stage or type of disease—which is fitly described as the “infantile type”—may be strikingly found in adults who, passing from primitive, more or less savage, life, come abruptly into close contact with massed infection in older countries. It was typically seen among native troops during the recent war—for example, the Senegalese troops in France. In his native country the Senegalese hardly suffers from tuberculosis. Its occurrence is limited to dwellers in more urban districts in contact with European settlers. The Senegalese troops recruited from such primitive regions were found on arrival in France—after minute examination—to be for the most part free from tuberculosis. Yet, notwithstanding the enforcement of good sanitary conditions, as typically in the Fréjus camp, where Professor Borrel made his observations, tuberculosis developed rapidly, with gross enlargement of lymphatic glands and grave toxic symptoms—commonly terminating fatally.

Passage from Lymphatic System.

The extension of infection from the glandular system to the viscera and blood stream does not call for detailed discussion on the present occasion. Suffice it to recall that extension may proceed along a variety of courses—for example, by way of the thoracic duct, or, more abruptly, by direct extension from an involved gland to other structure; by propinquity, as from glands to pleura or lung; or by more abrupt rupture of such gland into, it may be, a bronchus, with rapid widespread involvement of lung, or into a blood vessel, with the grave possibilities of generalized dissemination. On the details of such carriage I do not enter, as taking us beyond the limits of the present discussion. Much may be learned as to the possibilities of this extension from a study of the facts of comparative pathology.

Observations in the experimental animal and also in the slaughter-house point to the probability of the direct passage of the tubercle bacillus from one group of glands, in which individual glands have been successively invaded, to groups of glands in other regions, apparently by direct lymphatic connexion, and no less to the possibility of the passage of the bacillus from an adherent gland to a contiguous viscus. The deductions from such observations are endorsed by observations which have been recorded by various observers from autopsies in the human subject. The occurrence of direct spread from cervical glands downwards to thoracic and abdominal glands, and, conversely, a spread from abdominal glands upwards, may be accepted. The fact may be readily illustrated by comparing the results of inoculation—for example, of the guinea-pig—in one case in the groin, and in another case in the cervical region. While the ultimate result is a general involvement of the lymphatic glands, the sequence of events depends on the point of primary entrance.

SUMMARY.

In closing, let me rapidly recapitulate some of the chief points covered by this address towards which discussion may suitably be directed:

1. The part played by the lymphatic system in the early spread of tuberculosis requires to be emphasized.
2. Patients should be examined with that in mind, and the more important groups of glands should be systematically reviewed. In cases of general debility, all the readily accessible lymphatic glands should be carefully investigated.
3. In young children, the lymphatic system should be investigated with especial care, from time to time.
4. Lymphatic tuberculosis, conspicuous in children, becomes less marked in later life.
5. In cases of gross enlargement of one or more glands, exacting search should be made into the state of adjacent glands and other groups of glands.
6. Operative treatment should be limited to emergencies—for example, the immediate removal of an ugly deformity in

certain cases or the evacuation of an obviously softened land.

7. Save in exceptional cases, such operative treatment should not involve extensive incision.

8. Operative treatment should not be regarded as radical.

9. Tuberculous involvement of the lymphatic system can be effectively combated by continuous vaccine therapy.

SOME LOCAL RESULTS OF DENTAL INFECTION.

BY

W. G. SPENCER, M.S.,

SURGEON TO THE WESTMINSTER HOSPITAL.

I propose in this lecture to refer to various cases which have come under my notice during the year just past, in which local complications have been set up by infection arising in connexion with the teeth.

It will become evident to you that I have been greatly indebted to the teaching of the late Sir Henry Butlin, particularly concerning the way in which cancer of the tongue may be prevented, and also to that of Dr. William Hunter, consulting physician to Charing Cross Hospital, as to the manifold harm resulting from oral sepsis. The importance of Dr. Hunter's observations is shown by the number of communications which have appeared of late on the chronic general infections set up by oral sepsis—osteomyelitis, gastric and intestinal complications, septic anaemia, etc. Such chronic general infections are much more frequent and of greater importance than the local complications which I am about to mention, but these latter are at least troublesome, and may be dangerous, whilst I hope to show how they may be prevented.

Irritation by Tooth Plates.—Patients complain of stinging pain and tenderness along the sides of the tongue; there may be no apparent alteration of the surface epithelium, or merely this, that some papillae have become unduly prominent, in particular the line of papillae running forwards from the union of the anterior pillar of the fauces, in the rabbit called the foliate papillae, may be a little swollen. Close inspection may discover dental defects, and lead to explanation that there has been delay in carrying out what a dental surgeon had advised. But in many it is impossible to find anything wrong with the remaining teeth. I have had untold opportunities of confirming the note by Butlin on p. 126 of the second edition of *Diseases of the Tongue*, 1900, which refers to tooth plates made of irritating materials. The note commences:

"For some reason which I am not able to explain red vulcanite appears to me to act as a very decided irritant and exciter of chronic superficial glossitis."

In the middle of the note occurs this sentence:

"But the dental surgeons are by no means generally of my opinion."

No year has passed since that date but that patients have consulted me, and the persistent irritation has disappeared when the vulcanized rubber composition of the tooth plate has been replaced by metal. The black composition seems less often than the brown a cause of irritation. I do not know whether the irritant is a purely chemical one, such as a larger amount of sulphur used in vulcanizing, or whether a growth of micro-organisms occurs on the roughened surfaces, which cannot happen on smooth metal.

Herpetic eruptions are very painful when the corneous layer becomes detached and the persistent recurrence is very troublesome. It is quite useless to treat the middle-aged women, who are commonly the sufferers, for dyspepsia, neuralgia, and anaemia, unless all causes of dental irritation are removed first of all. Generally the outstanding dental treatment over which difficulty arises is that for the relief of pyorrhoea alveolaris affecting the lower incisor teeth; anything short of extraction may be unsatisfactory.

Precancerous Lesions.

Causes of patches of leucoplakia, papillomas, fissures, and chronic ulcers on the tongue and inside of the cheeks have of late years diminished. The clay pipe has become almost obsolete; tobacco, whether smoked in pipes, cigarettes or cigars, seems to give rise to much less irritation than was

the case formerly, and most people, when any irritation is experienced, are wise enough to stop smoking, or to change the kind of tobacco. Only in the East, where tobacco is mixed with caustic lime and betel nut, and held in the mouth as a quid, is there any regular sequence of cancer. Of course this refers to tobacco when there is no other lesion present, for, although it is a matter on which it is difficult to speak with precision, smoking indefinitely increases the general effects of oral sepsis arising from the teeth.

Syphilis as an antecedent to cancer of the tongue has been influenced of late by the arsenical treatment; early superficial glossitis is quickly removed, and is thus prevented from going on to a definite leucoplakia, which neither mercury nor arsenic can remove. Against the improvement by the more rapid removal of early secondary manifestations is the uncertainty how far an advance has been made in the actual curing of syphilis. The effect of salvarsan and its substitutes in causing the rapid disappearance of the primary and secondary manifestations of syphilis may prove misleading, and prevent the carrying out of a prolonged course of treatment by mercury.

The practice of applying caustic to sores on the tongue continues; I am quite sure that caustic determines the commencement of those changes by which a chronic inflammation passes over into cancer.

There is one way in which cancer of the tongue can be prevented—namely, by the patient, or the first doctor he consults, or both, taking into account any lesion on the tongue, and in the mouth, as seriously as if it were an acute disease, to be kept continuously under observation until it has entirely disappeared, or has been cut out. I have never seen a case of cancer of the tongue or mouth, in a patient over 30 years of age, in which there has not been a definite history of a preceding inflammatory stage, during which interval the lesion might have been made to disappear, or it might have been removed by a slight operation.

In some cases, no doubt, the failure as to this lies with the patient, but it is a regular feature of the history of cases of cancer of the tongue that the impression made on the patient by the first doctor consulted has been that the condition was both trivial and transient. The doctor, however, failed to make the patient understand that for the trouble to be trivial and transient the patch should entirely disappear in a few days. The doctor did not tell the patient that every inflammatory condition affecting the mouth and tongue should under treatment completely disappear within three weeks, and that, if it should not do so, it should be removed by a superficial excision, and the wound so made closed by suture.

Complete disappearance implies that not only is any breach of surface covered by healthy epithelium, along with cessation of all pain and tenderness, but there should persist no subepithelial induration. If such epithelial induration is examined under the microscope it will be seen that a chronic inflammation is continuing which affects the epithelium from below. Hence an epithelioma can be started from below whilst the epithelial surface is apparently intact, just as well as when the epithelial surface is continually irritated by a jagged tooth.

The excision of patches of leucoplakia, fissures, subepithelial induration, nodules, warts, scars, and chronic ulcerations, however caused, followed by suture, is a completely successful procedure. The operation is attended by no danger, and as the removal involves only the epithelium, there is no impairment of the movements of the tongue.

Where there is subepithelial induration it is difficult to distinguish chronic inflammation from early malignant disease. Therefore when a patch has been removed and submitted to a microscopical examination, if in addition to epithelial overgrowth and subepithelial infiltration by small round cells, there has already set in a downgrowth of epithelial columns, the lymphatic glands, together with the external part of the submaxillary salivary gland, should be at once dissected out from the corresponding anterior carotid triangle. In such cases the lymphatic glands will generally show an increase of small round cells in the lymph spaces of the gland and its capsule, but definite epitheliomatous cells may not be recognizable. Exceptionally, when the patch removed has been situated across the middle line, the dissection has to be done in both anterior carotid triangles. Such operations are safe as regards life; there is little trouble after the operation, and that for a few days only, after which the patient is freed from anxiety, immediate and prospective. The scar of the incision in the neck becomes less obvious than one after removal of tuberculous glands.

* The Second Hunterian Society Lecture, delivered on January 11th, 1922.

When leucoplakia has been insufficiently treated and has spread widely over the surface of the tongue, an exceptionally extensive removal of epithelium may entail some impairment of the movement of the tongue, which, however, in course of time tends to disappear. There are also a few cases in which leucoplakia reappears on previously sound areas of mucous membrane, but if the patient submits to a repetition of excision of affected epithelium he escapes cancer.

Salivary Gland Infection.

Oral sepsis may penetrate the sphincters which close the orifices of the ducts of the parotid and submaxillary salivary glands, and set up a chronic inflammation in the walls of the ducts and in the substance of the gland. Acute septic infection, which in former days was common in the parotid, and generally fatal, has now become rare because among the duties of the nurses attending exhausted medical and surgical patients is that of keeping the mouth and teeth as clean as possible. The cases of chronic septic infection from the mouth commence by an induration of the papilla marking the orifice of the parotid or submaxillary duct; the duct itself becomes a thickened and painful cord, and it dilates during secretion, with an increase of pain. In the submaxillary duct a concretion may form, either a stationary large one, of the shape of a date stone, or one or more small ones which move in the duct backwards and forwards. Wherever situated, the calculus is the seat of great tenderness. If the infection spreads to the gland there is pain and tenderness, increased during salivary secretion. The following cases have been observed recently:

CASE I.

The patient complained of intermittent pain and swelling in the right parotid gland and along the line of the duct. The orifice of the duct formed a tender indurated nodule; a cord was felt along the line of the duct, at one point about the socia parotidis there was a cystic swelling. A caualiculus probe-pointed director was with difficulty passed up the line of the duct, and the duct slit up into the mouth as far as the anterior border of the masseter.

CASE II.

A patient had a parotid fistula over the position of the socia parotidis, the indurated papilla in the mouth had become impermeable to a probe passed from that direction. Therefore the probe-pointed director was passed from the fistula on the cheek down the duct into the mouth, and guided by it a second probe-pointed director could then be passed up the duct to a point beyond the fistulous opening. Thus guided the parotid duct was slit up into the mouth to a point nearer the gland than the fistulous orifice. The margin of the fistula having been then pared, and closed by clips, healing of the cheek occurred by first intention.

CASE III.

There was intense pain and tenderness at times along the line of the right submaxillary duct, which prevented the use of a lower tooth plate. The special point of tenderness shifted, at one time being just in front of the anterior pillar of the fauces, at another time right over the canine tooth. This sign was recognized as caused by a minute concretion moving its position in the duct; it could not escape because the papilla had become indurated and the orifice stenosed. The probe-pointed caualiculus director was passed with difficulty into and along the duct, which was then slit up as far as the intrabuccal portion of the submaxillary salivary gland. When seen a month later the saliva was being discharged directly from the gland into the mouth; the tenderness of the external portion of the submaxillary gland had been relieved; there was still some swelling and tenderness in the sublingual gland situated underneath the slit-up duct.

CASE IV.

When the septic inflammation has extended to the extrabuccal portion of the submaxillary salivary gland, and this has not been relieved by slitting up the duct and subsequent massage to the gland, it has been necessary to remove the submaxillary salivary gland through an external incision. Glands so removed show chronic interalveolar fibrosis with dilatation of alveoli and of smaller ducts, many of which contain inspissated mucus in which calcareous material is deposited. A severe case of oral sepsis was started years ago, especially by pyorrhoea alveolaris affecting the lower incisor teeth. Both submaxillary salivary glands and the ducts were infected and also there was excited gastro-duodenal ulceration. The patient has had to undergo a series of operations on different occasions, the excision through the mouth of one, and then of the other thickened and dilated Wharton's duct, as far back as the gland; later the excision of the submaxillary gland on each side through an external incision; finally, gastro-jejunostomy to remove the gastric trouble. In addition all the teeth were removed and dentures fitted with considerable difficulty.

Acute Suppuration following Extraction of Teeth.

It may be described as the common procedure to extract one or more carious teeth, although there are present additional causes of oral sepsis. Any septic complication is so rare as to be negligible.

In the four cases I mention the extraction of two or three molars with all ordinary care was followed by acute suppuration. I believe that an acute septic infection of the raw surfaces of the gum and of the bare alveoli which followed the extraction in these cases was derived from the lower incisor teeth already affected by some degree of pyorrhoea. The character of the suppuration corresponded with that set up by virulent streptococci, mixed with staphylococci.

CASE I.

A female had become anæmic, for which there was no other evident cause than the state of her teeth. Three left lower molars were extracted, leaving eight teeth affected by pyorrhoea and some by caries. An acute septicaemia supervened at once, the temperature rising to 105° F. and the pulse to 130. There appeared an acute brawny oedema extending from the jaw to the clavicle on the side of the extraction. Under the presumption that the most dangerous part of the infection was due to streptococci, a 20 c.cm. dose of an antistreptococcal serum was administered every six hours for four doses. Meanwhile the exceedingly foul condition of the mouth was reduced by repeated cleaning and irrigation. The spread of the inflammation was arrested and suppuration supervened, fortunately superficial to the deep fascia. Under a general anaesthetic all the remaining teeth were removed by first wiping out the gum pockets around the teeth with iodine, and after extraction applying iodine to the alveolus. Then a long incision over the anterior carotid triangle laid open the suppuration. Healing followed without any reaction subsequent to the operation.

CASE II.

A female, after extraction, had acute inflammation below the jaw, which became circumscribed to the submental gland and to the gland over the bifurcation of the carotid on the corresponding side. All the rest of the teeth were sound except the lower incisors, which presented pyorrhoea alveolaris. The removal of these incisors and the opening of the abscesses had the same result as in the previous case.

CASE III.

A male, aged 50, had had oral sepsis for a long while. He was markedly thin and anæmic, for which there was no other evident cause. A couple of lower molars were extracted, following upon which he was attacked by septicaemia, attended by pain, sleeplessness, loss of appetite, and weakness. Suppuration started in the alveoli from which the teeth had been removed; internally pus spread forwards under the gum, externally there was inflammatory induration limited to the line of the horizontal ramus of the mandible. There was marked pyorrhoea alveolaris affecting the lower incisor teeth. Incisions were made through the gum from within the mouth, and suppurating cavities repeatedly syringed out. Later the incisor teeth were removed; the necrosis remained limited to the alveoli, and there was no extension to the neck. Convalescence was slow.

CASE IV.

This case ended fatally. A male, aged 40, had had some oral sepsis for probably ten years, and two or three carious teeth had been previously extracted without complications following. Then three molar teeth were removed from the lower jaw on the left side, and the patient went straight back to his office to work. Acute septicaemia followed, and three days after the extraction he was sitting up in bed with laryngeal stridor, the voice almost lost, swallowing with difficulty, temperature 105°, pulse 116, respiration normal in rate. The mouth was excessively foul; there was brawny oedema from the lower jaw to the clavicle on the left side. Injections of antistreptococcal serum were followed by relief to the laryngeal stridor, but signs of purulent bronchitis continued. Four days after extraction the foulness of the mouth had not been reduced in spite of the cleaning by the nurses. The brawny oedema of the neck had gone on to suppuration under the deep fascia. There was a limited necrosis of the jaw around the site of the extraction.

Under a general anaesthetic the remaining teeth, ten in number, were extracted whilst applying iodine as described above. Every tooth stank, more especially the lower incisors. Four incisions were made in the neck and tubes inserted; foul pus escaped. The result was an immediate improvement in the condition of the mouth; the necrosis of the jaw did not extend; foul pus and sloughs of fascia were discharged from the incision in the neck, but the purulent

Ten days after the original extraction, and removal of the rest of the teeth, a little bright blood appeared with the pus and sloughs, so the drainage tubes were removed. Signs of a left-sided pleurisy being confirmed in consultation with a physician, on the eleventh day 15 oz. of turbid fluid were aspirated from the left pleura and found to be swarming with streptococci. Later, on the same day, the left pleura having again filled and the breathing and pulse becoming impaired, he was being carried into the operating theatre when suddenly the mouth was filled with blood and blood escaped from the neck. This was checked by thrusting a finger into a submaxillary incision and another through the mouth into the necrosing area around the jaw. An enlargement of the incision in the neck exposed facial blood vessels in the midst of foul granulations. The haemorrhage was apparently derived from both an artery and vein and was controlled by clamps. After this the fluid was let out from the pleura. The patient died ten minutes after his return to bed.

There are two ways of regarding these four cases. They may be considered exceptional occurrences, and many objec-

tions may be raised to the removal of the lower incisor teeth. On the other hand, when affected by only a slight degree of pyorrhoea, the lower incisors may become the source of a violent infective agent, independent of the quantity of pus discharged, in particular as the focus from which a streptococcal infection may arise. Granted this, it may be best to extract these teeth first, and after the oral sepsis has been reduced remove the more deeply rooted teeth.

I have many times removed a number of teeth at one operation without noting shock or inflammatory reaction, but rather an immediate relief of the oral sepsis. The cases have, however, been treated like others undergoing major operations, including preliminary preparations, a general anaesthetic, disinfection, and extraction of a tooth at a time, and after-treatment in bed.

FEBRICULA AND INFLUENZA.

BY

A. I. SIMEY, M.D. CANTAB., M.R.C.P.

MEDICAL OFFICER TO NURSEY SCHOOL, AND PHYSICIAN TO THE HOSPITAL
OF ST. CROSS, REGENT.

In every great boarding-school there occur from time to time—and usually no term is quite exempt—a certain number of cases of a complaint popularly spoken of as “a chill” or “the flu,” or, if much more severe, “influenza,” and characterized in its simplest form by sudden onset, usually a shivering attack, and pains in the head, back, and limbs. Sometimes there is slight sore throat and a mild adenitis, with nothing but a little redness of the fauces to be seen, and the patients have perhaps only recently got rid of a slight cold and cough; but there is rarely much catarrh when they seek advice, nor, apart from the pyrexia and slight rise of pulse rate, is there any physical sign to account for the condition. After a few days in bed, the administration of a purge, gargle, and ammoniated quinine or some simple diaphoretic, the temperature drops either suddenly or by a descending zigzag to normal, and the attack is over. Such is the disease in its simplest form.

My object is to describe this disease and its varieties, and to establish its relation to certain allied conditions—namely, erysipelatous catarrh, and influenza—and to consider the etiology, pathology, complications, and some points in the treatment of patients in whom they occur.

Sir William Osler, in his *Principles and Practice of Medicine*, describes febricula as “fever of slight duration, probably depending upon a variety of causes.” A febrile paroxysm lasting twenty-four hours and disappearing completely is spoken of as “ephemeral fever.” If it persists for three, four, or more days without local affection it is referred to as “febricula.”

In the first place, it is obvious that the disease, which should be spoken of as febricula, is an infection, and may occur in mild or severe form; it has certain definite types and complications, depending, no doubt, partly on the strain and virulence of the micro-organisms concerned in any particular epidemic, and partly on the admixture of the micro-organisms and the introduction of new strains, and possibly also new species. Climatic conditions are also a factor in determining the prevailing manifestations of the disease.

There are four main types commonly seen:

In the commonest the onset is sudden, and the symptoms which have already been described very soon yield to treatment. The temperature chart is characteristic of the descending see-saw type, with about 1 to 2 degrees between the evening and morning records, normal being reached on the fourth, fifth, or sixth day; then follows a short period of subnormal morning temperatures with normal, or slightly above normal, evening records, then a continuous normal or subnormal temperature till convalescence is attained.

In the second type the temperature chart is more like that of a lobar pneumonia of three to five days' duration, with a sudden drop resembling the crisis in pneumonia, and often followed by a post-critical rise.

In the third type the temperature is far more irregular, beginning like a mild attack of the second type, then, after two or three days' normal temperature, relapsing and repeating the phenomena of the early period on a modified and milder scale. There may be several such relapses, or “exacerbations,” the chart reminding one of a short attack of trench fever.

In the fourth type the chart resembles that of a mild enteric infection with high evening and much lower morning temperatures, but usually a steady rocking, descending swing, the steps becoming smaller and smaller until the normal or sub-normal is reached in from ten to fourteen days.

The striking peculiarities of the disease are the absence of acute symptoms after the first few days, the cleanliness of the tongue, the keenness of appetite, and the rapid recovery. In schoolboys very few seem to be much debilitated by a moderate attack, and they find their legs again with striking rapidity, and need considerable supervision and restraint to prevent them returning to full exercise sooner than is safe. In spite of this they lose weight rapidly, but gain it as quickly under favourable conditions.

Such are the main types of this disease; one may almost predict from the first few cases which occur in a school in a given term to which of the types the outbreak is likely to conform. Once it has started it spreads with more or less rapidity by boarding-houses chiefly (because the infection is mainly a dormitory or study infection), then by forms and classes. The rate with which it spreads depends on several factors, chief of which are: (1) The number of individuals who are partially or completely immune owing to a recent attack, or to prophylactic vaccination; (2) the severity of the weather and the precautions taken to ensure against overcrowding and unnecessary exposure to wet, cold, and overexertion.

Complications.

There are certain phenomena which occur in the course of epidemics of febricula which hardly deserve the title of complications, being rather a part of the disease.

The chief are as follows:

Epistaxis.—Of very common occurrence, especially in the early stages.

Pharyngitis.—Is very common; the appearance of the tonsils is that of raw meat, the soft palate is scarlet, and “sore throat” is complained of.

Tonsillitis.—Is not often severe. In some epidemics cases of true follicular tonsillitis occur, but this is not the rule; occasionally quinsies develop, but not as a rule except in individuals predisposed to their occurrence.

Ear complications are unfortunately far from uncommon; there are two main forms:

1. Those beginning with Eustachian catarrh, and then developing otitis media with acute earache of a most distressing kind, unaccompanied by severe constitutional symptoms and high temperature. This may subside without perforation of the drum, but frequently relief occurs when otorrhoea appears with a discharge often serous for a short time, but usually becoming purulent within thirty-six hours. The pus contains the micro-organisms which are probably the cause of the disease, reference to which will be made later on, and it is likely that futile attempts to blow a completely blocked nose lead to the infection of the middle ear.

2. Those beginning without Eustachian catarrh, the first symptoms being earache, the drum becoming oedematous, with redness and loss of the usual landmarks. In some cases a blister forms on the outside of the drum, bursts, and discharges a pale thin watery fluid, and the attack is over in two or three days without further discharge. In such cases the walls of the auditory meatus often share in the inflammation, and the middle ear seems to escape.

Conjunctivitis is not at all uncommon, infection taking place through the nasal ducts. In some cases this conjunctivitis is most persistent and only cured by syringing out the ducts and douching the nose, in addition to treatment of the eyes with boracic lotion and protargol, or silver nitrate drops.

Adenitis in a slight degree is common; in cases where the throat is more than usually inflamed it is generally more severe. In individuals whose glands are usually somewhat enlarged, possibly owing to a tuberculous tendency, adenitis is much more marked.

Abdominal Complications.—Constipation is the rule whilst the temperature is high. Vomiting is rare, but occurs. In some epidemics the stomacheic symptoms are much more marked than in others, hence the term “abdominal influenza.” Jaundice is by no means an uncommon complication, occurring either as a late phenomenon or quite early. In certain epidemics of febricula small outbreaks of jaundice occur, and I cannot but think that they are not remotely allied in origin.

Cardiac complications are rare. Endocarditis very seldom occurs. A muscular weakness of the heart muscle, giving rise to a soft systolic murmur in the dorsal position, is quite common and lasts long into convalescence. Occasionally cardiac dilatation and hypertrophy persist, and require prolonged and persistent care. Rapidly and irregularly of the pulse and uncommonly persist even after convalescence seems to be established. Convalescents should return to exercise very gradually; in a mild attack not for at least three weeks from the onset of the disease.

Pulmonary complications are common in some epidemics, rare in others. Whilst lobar pneumonia is rare, bronchopneumonia and bronchitis are not at all uncommon. Plural effusions are comparatively rare, but occur. In severe cases empyema may follow. In many cases there is a localized congestion at the base of one lung without any dullness or solidification; it is accompanied by cough, but no dyspnoea, and the symptoms are not those of bronchopneumonia, there being neither distress nor cyanosis nor great rapidity of respiration. A dry pleurisy sometimes occurs. In patients liable to asthma, an attack of asthma may supervene.

Nervous Phenomena.—Of these neuralgia is by far the commonest; it is usually unilateral, affecting the supraorbital and, less commonly, the infraorbital branches of the fifth nerve. Sometimes it is most persistent and causes sleeplessness, which may lead to serious depression of spirits. Occasionally there are signs of a frontal sinusitis. Great relief is afforded by hot dry applications and administration of caffeine, aspirin, and phenacetin in suitable doses. Delirium is uncommon, but nightmares are common, and somnambulism occurs amongst those in whose family there is a history of epilepsy or its allies, sometimes very remote. Meningitis is rare, and, when it occurs, usually accompanies otitis media, without necessarily the formation of abscess.

Arthritis and nephritis never occur, but a transient albuminuria is common.

Diagnosis.

The diagnosis is usually easy, especially after three or four days of observation. The following are the conditions which must be borne in mind in the early stages:

1. The onset of one of the specific fevers, especially measles.
2. Enteric or paratyphoid fevers. This can be settled later on by agglutination tests. In the early stages a blood culture should be taken if there is any strong suspicion or history which would make the occurrence of these diseases probable.
3. In some cases of early phthisis attacks of this nature occur which may possibly be due to the spread of a tuberculous focus.
4. In some cases of gall stones attacks of cholecystitis occur with very similar symptoms, and not necessarily accompanied by jaundice.

Incidence and Immunity.

The disease is now endemic, with exacerbations at intervals when circumstances are favourable to its appearance in epidemic form, and the number of individuals whom a recent attack has rendered temporarily immune is comparatively low. The following figures will be useful by way of illustration, signifying the number of cases occurring during ten years at Rugby School since 1911, the number of boarders being approximately 550.

Year.	Term.	Cases.	Year.	Term.	Cases.
1911.	Lent ...	19	1916.	Lent ...	4
	Trinity ...	27		Trinity ...	34
	Christmas ...	8		Christmas ...	?
1912.	Lent ...	129	1917.	Lent ...	?
	Trinity ...	40		Trinity ...	?
	Christmas ...	21		Christmas ...	23
1913.	Lent ...	42	1918.	Lent ...	22
	Trinity ...	23		Trinity ...	187
	Christmas ...	23		Christmas ...	17
1914.	Lent ...	46	1919.	Lent ...	113
	Trinity ...	39		Trinity ...	21
	Christmas ...	2		Christmas ...	31
1915.	Lent ...	150	1920.	Lent ...	35
	Trinity ...	32		Trinity ...	261
	Christmas ...	31		Christmas ...	40

During the summer term of 1918 there was a considerable outbreak of febricula in Rugby School, and one may safely say that every boarder was exposed to the infection; 187 cases were admitted to the school sanatorium, or, roughly speaking, one-third of the school succumbed during the term; whilst others, amounting perhaps to 250 in all, contracted it during the holidays.

In the following winter term, when influenza in its severest form was epidemic everywhere, and especially severe in the Rugby district, there was not a single case among the schoolboys, and only 17 cases of a mild "febricula" were admitted into the sanatorium. Of these 17 boys, 4 were amongst those who had contracted it in the previous term. It is noteworthy that no restrictions were imposed upon the school which could possibly have prevented the infection being introduced from the town and neighbouring district into the boarding-houses.

During the next term, when another wave of influenza of severe type passed over the district, the school was again visited by febricula in epidemic form. Of the 187 boys who had contracted it during 1918 Trinity term, 170 still remained in the school, and of these, 31 succumbed out of a total of about 140 cases admitted.

From a consideration of those statistics and a careful examination of a large number of individual cases I have arrived at the following conclusions:

1. That an attack of febricula renders most patients temporarily immune to febricula and influenza.
2. That such immunity lasts from three to nine months, differing (a) in different individuals, (b) according to the severity of the original attack.
3. That there are some few individuals who are (a) highly immune to both diseases; (b) highly susceptible to both diseases, and in these individuals one attack conveys very little immunity against a second, such attacks sometimes following closely upon one another; (c) highly infectious to others when suffering from even mild catarrh—in fact, "carriers."
4. That some individuals who are liable to asthma, bronchitis, or febrile colds, with or without sore throats, appear to be free from typical attacks of febricula, the reason, no doubt, being that

bacteriologically the same or a similar infection is the cause of all these phenomena, which differ rather in the site and vulnerability of the affected tissues than in the infection which disturbs them.

5. That febricula is closely allied to coryza and febrile colds on the one hand, and to influenza, whether "Spanish," "Russian," or "English" in its origin, on the other hand.

It seems highly probable that coryza, febricula, and influenza are an inseparable group of diseases beginning in the upper respiratory passages. If the infecting micro-organisms meet with sufficient resistance locally coryza is produced, exudation is profuse, and the infection is dealt with locally. If, on the other hand, the infection rapidly becomes systemic, there is usually little catarrh, but serious constitutional symptoms with an acute toxæmia or septicæmia appears; in other words, the disease is now "influenza."

As to what determines the clinical phenomena I would suggest that the following three considerations are of great importance:

- (i) The relative proportions of the chief infecting organisms present in any given epidemic—that is, streptococcus, pneumococcus, *B. catarrhalis*, *B. influenzae*.
- (ii) The presence of other "contaminating" micro-organisms whose activities increase, diminish, or in some way modify the infection.
- (iii) The "strains" of these varying micro-organisms and the exaltation or attenuation of their virulence or modification in some other direction by the passage through the bodies of their hosts, whether human or otherwise.

An illustration may be drawn from chemistry. The particular properties of a chemical mixture depend very largely, not only on the particular constituents of which the mixture is composed, but also on the proportions in which these constituents are present. Thus ordinary gunpowder consists of the three constituents carbon, sulphur, nitre; but it is only when these three are thoroughly mixed together in certain definite proportions that the full "fighting efficiency" of the mixture is realized. If one or other of the constituents is increased and allowed to preponderate beyond the proportion required for maximum efficiency, the property of the combination is much modified and only "a sort of gunpowder" results.

Hence we are driven to the logical conclusion that "influenza" is a clinical term and not a distinct disease, and although the bacillus of Pfeiffer is almost invariably present, it is not the sole cause of the symptoms, but is only one of an innumerable variety of factors which, taken together, give rise to the alarming phenomena with which we are only too familiar. It is, so to speak, one step worse than febricula, which protects against influenza because it neutralizes the greater portion of the influenza toxins.

It is well known that the influenza bacillus is found in some cases of nasal catarrh, and is a constituent of many stock anti-catarrh vaccines; it is also found in the expectoration of patients suffering from febricula who present no physical signs of pulmonary disease.

Treatment.

I have already referred to the simple treatment of ordinary cases of febricula, and it is not my intention to deal any further with general and drug treatment, but it is necessary to speak of the use of vaccines in these closely allied conditions. There are two methods of vaccine treatment:

1. Prophylactic vaccines.
2. Remedial vaccines.

In both great successes have justly been claimed and in both failures must frankly be admitted. So far as my own experience goes, the prophylactic treatment is much more encouraging than the therapeutic.

For prophylactic purposes one may use (a) a stock vaccine, of which there are many good recognized preparations, or (b) a "local prophylactic" vaccine. This means, in the case of a school or other concentrated community, a vaccine prepared by swabbing the throat and noses of affected patients and by adding strains obtained from their sputum to the resulting cultures. Such a vaccine is reinforced or modified from time to time by the addition of fresh strains from new cases and kept up to date. It is best administered during the holidays in two doses of increasing strength with a fortnight's interval, and it is probable that the susceptibility to infection is slightly increased after the first dose. It is chiefly on this account that it is advisable to administer the doses in the holiday time, when the chance of exposure to infection can be minimized, and when rest and warmth after the first dose are more easily obtained than at school. Stock vaccines are sometimes efficacious, especially the polyvalent varieties, but their success is more a matter of chance. They should be employed only when, for some good reason, it is not practicable to obtain a local prophylactic vaccine or when success with a particular stock has been proved to be efficacious in a particular type of the disease.

Therapeutically, autogenous vaccines are far preferable to others, but owing to the delay necessitated by their preparation it is often imperative to begin with a stock vaccine. By the time the autogenous vaccine is ready for use it may be too late, and the patient may not be in a condition necessitating such treatment. Still, the possession of an autogenous vaccine made from a given patient is useful for the direct contacts of the patient from whom it is obtained, and possibly also, in a less degree, for the more remote contacts.

In a localized epidemic local prophylactic vaccines should constantly be prepared for future use, so that pace may be kept with the modification of the strain as it passes through individual after individual.

Conclusions.

1. The influenzoid group of diseases may be subdivided for clinical convenience into two groups:

(a) Localized infections, with slight toxæmia—namely, coryza, catarrh.

(b) General infections, with much toxæmia and possibly septicæmia—namely, febricula, influenza.

2. The severity of symptoms in the second group depends partly on the susceptibility of the patient and partly upon the proportions of the various micro-organisms present, their strains, and the contaminating organisms present. It may be that there are some ultra-microscopic micro-organisms of whose existence we are, as yet, unaware, but I cannot help thinking that the bacillus of Pfeiffer is rightly named *B. influenzae*.

3. Partial and temporary immunity is conferred by an attack of febricula against influenza and by influenza against febricula.

4. Vaccines therefore, to be most efficacious, should be specially prepared from local material, and in an epidemic these vaccines should be systematically reinforced to keep pace progressively with the advance of the disease.

* For permission to publish these statistics I am indebted to the Right Rev. A. A. David, D.D., late Head Master of Rugby School.

SPASMODIC STRICTURE OF THE UTERUS.*

BY

Mrs. M. A. DOBBIN CRAWFORD, M.D., M.A.O., F.R.C.S.I.

THE tonic contraction of a zone of circular fibres in the uterus was formerly described as hour-glass uterus. This term is not satisfactory, for, although it gives an accurate picture of the interior of the uterus, the general impression conveyed is false, for the exterior of the uterus remains ovoid in contour and the narrowing of the lumen is not, as a rule, perceptible by abdominal palpation or inspection. The condition may also be described as localized tetanus of the uterus; in some types the clinical picture very closely resembles that of tetanus uteri, particularly in the later stages.

Many other terms have been applied to this condition, as Schroeder's ring, Müller's ring, retraction ring, the last of which has been discarded. Eardley Holland's definition, "the active retention of the foetus by the uterus," omits the third stage of labour altogether. I prefer the more convenient term, "spasmodic stricture of the uterus," or, for short, the less definite term used by De Lee, "strictura uteri."

I would urge that the term be applied only to those cases in which the contraction ring is the cause of difficult labour, no other obstruction being present. Where there is other cause of obstruction, and the lower uterine segment is stretched, the term retraction ring should be used.

Eardley Holland has under this heading reported two cases of shoulder presentation with prolapsed arm, where the lower uterine segment was greatly lengthened, and where at the Caesarean section great difficulty was found in extracting the child, owing to the tonic contraction of a ring of muscle. Personally, I should describe these as cases of obstructed labour with well-marked retraction ring.

History.—The earliest report found of this condition was by Smellie in 1743, in his *Collection of Preternatural Cases and Observations in Midwifery*. He describes his case as "a

laborious one; the uterus contracted before the shoulders of the foetus."

Since 1907, when Andrews and Maxwell drew the attention of the Royal Society of Medicine to this condition as a cause of dystocia, the subject has been discussed from time to time, and a comprehensive survey of the literature was made by Clifford White in 1923.

Etiology.—The cause is unknown. It is assumed to be some abnormal irritation or irritability of the uterine wall. It is said to occur most frequently in neurasthenic primiparae, and to be associated with malpresentations, premature rupture of the membranes, uterine inertia, prolonged first stage, with repeated vaginal examinations or attempts at manual or hydrostatic dilatation of the cervix. None of these associated conditions were present in my case.

With regard to parity, Clifford White found that the condition occurred twice as frequently in multiparae as in primiparae.

Types.—*Strictura uteri* or hour-glass uterus has been most frequently described as occurring in the third stage of labour and causing incarceration of the placenta, formerly due in many cases to unwise administration of ergot. I have seen this occur, too, after an injection of pituitary extract during the third stage in an attempt to hasten a dilatory placenta. The spasm, however, may occur during any stage of labour and at any part of the uterus. It will then be as follows:

1. In front of the whole child.

2. Around some part of the child, as in my own and the majority of cases, around the neck and obstructing the shoulders; or, as in a case reported of breech presentation, around the arms and body. Lady Barrett has reported a case where the ring was formed around the neck of a hydrocephalic foetus presenting by the breech.

3. Following one twin and ahead of the second child.

The Contraction Ring.—As regards position, although it is certainly true that the ring may form at any part of the uterus yet it has most usually occurred at the level of Bandl's ring—that is, where the upper and lower uterine segments meet; hence the confusion as to nomenclature. The contraction ring may run very obliquely across the uterus, as in that case reported by Clifford White where it corresponded to the groove between the thigh and body of the child. He considers that the contraction ring is largely formed by the close moulding of the uterus to the foetus, and doubtless this is true in those cases where the membranes have ruptured early and the liquor amnii has drained away. Jardine states that in all his cases where the ring has been situated around the neck of the child the membranes have ruptured before labour has begun at all. These observations do not apply to my case, in which the membranes had to be ruptured artificially.

Mortality.—The condition is very serious. Hedley gives the maternal mortality as 40 to 50 per cent., the foetal mortality as 60 per cent., and states that 10 per cent. of the foetuses are macerated. The child dies of asphyxia, the contracted muscle interfering with the oxygenation of the foetal blood. The same circulatory disturbance allows infection of the uterus and its contents to occur, and the woman may die of sepsis or exhaustion.

Report of Case.

The patient, Mrs. B., a quartipara, gave the following history of previous labours:

1. In labour for three days and nights; child born alive; forceps.

2. Twos. One born alive, but died in a few minutes. forceps. The other had to be taken away, was born dead, and disposed of without either parent being allowed to see it.

3. Child born alive, 9 lb. weight; forceps. Subsequently the patient spent five weeks in hospital for repair of complete perineal tear.

Her mother told me that all these labours had been prolonged and very difficult, that the doctor had said that there was "a shelf inside her," preventing the birth. This appears to me to suggest strongly that the uterine condition was habitual to this patient with every labour. I was therefore prepared for trouble, but when I saw the patient a few days prior to labour I could find nothing abnormal. The child was presenting by the vertex, and the pelvis showed no sign of contraction. The abdomen was pendulous; I judged that there was a large quantity of liquor amnii, and the woman had insisted upon doing heavy housework, such as scrubbing, up to the last without wearing any abdominal belt or other support.

Labour started at midnight, but the pains were very slight for some hours. I was called at 8 a.m. The patient was still in the first stage, the os dilating slowly, membranes intact. She had been up all night, so I gave her 1½ grain of morphine and left with instructions that she was to go to bed and sleep. I returned at 11,

* Read before the North of England Obstetrical and Gynaecological Society at Sheffield, November 18th, 1921.

and found the nurse very worried; she said that the patient had been in great agony; the patient herself said that the pain was continuous and very severe. For a while the pain appeared to be due to tonic contractions of the uterus, the contractions increasing and then diminishing, but never completely relaxing. The woman's general condition was extremely good; but she was obviously in tremendous pain.

The cervix being three-quarters dilated, I ruptured the membranes and waited for the head to fix, keeping the patient quiet with chloroform for about two hours. It was now thirteen hours since the onset of labour; the head showed no sign of fixing, but was balloting freely in the pelvic brim, and as I could perceive no cause for the delay I determined to make an intrauterine examination under full anaesthesia. This I did under ether, and found the following state of affairs:

The cervix was fully dilated and empty, the free edge hanging flaccid in the upper part of the vagina. During each pain the head would descend into the cervix only to recede again with equal regularity. I palpated the head, which was normal and presenting by the vertex. The pelvis was very roomy. Without any difficulty I passed my hand up beside the head and found that the uterine muscle was firmly contracted in a ring around the child's neck. Having passed the tip of one finger through this ring to confirm the diagnosis I withdrew to consider the position.

Both mother and child were in very good condition, but the contraction ring must now have persisted for some hours in spite of morphine and prolonged chloroform followed by deep ether anaesthesia, and as the force and frequency of the contractions were really alarming I decided to have the patient moved into hospital, where if the spasm did not relax within a reasonable time the operation of Caesarean section would be available.

The patient was not allowed to regain consciousness, but was kept quiet with chloroform until shortly before her arrival at hospital about one and a half hours later, when the supply gave out. As the ambulance drew up at the hospital door the child was born spontaneously—a healthy boy weighing 9 lb.

The subsequent history was uneventful; the patient was up and out on the eleventh day.

Remarks.

There are a few points in the case which I think deserve emphasis:

As regards the suggestion that the condition was habitual, one case has been reported where the contraction ring occurred at three successive labours in the same patient.

The symptoms are confusing. One does not expect to find a tight contraction ring in a patient who is obviously not threatened with rupture of the uterus, in a patient having a roomy pelvis and carrying a normal child in a normal position. However, it is just under these circumstances, where labour is unwarrantably prolonged, that one should suspect the presence of

The following symptoms struck me as most obvious:

- (a) Contractions very strong, frequent and painful, for a while practically continuous; uterus very tender.
- (b) No distension of lower uterine segment; contraction ring neither visible nor palpable externally.
- (c) The head balloting freely in the pelvic brim, advancing and retiring again with each pain.
- (d) The woman's general condition extremely good.

I have tabulated these symptoms for comparison with those commonly found in obstructed labour with threatened rupture of the uterus, as described by Tweedy.

OBSTRUCTED LABOUR. Retraction Ring.	SPASMODIC STRICTURE. Contraction Ring.
1. Vagina hot, dry, walls swollen, lips oedematous.	1. For some hours vagina remains moist and introitus normal.
2. Vagina ballooned, fornices pulled up.	2. No ballooning nor stretching of fornices.
3. Cervix may be fully dilated and drawn completely up, or may be imprisoned in pelvis, thickened and swollen from oedema and effusion of blood.	3. Cervix flaccid, empty, hanging loose in folds, no signs of pressure.
4. Contractions continuous or almost so, fundus and especially lower uterine segment very tender.	4. Contractions continuous or almost so, very powerful, tenderness marked.
5. Lower uterine segment becomes progressively distended, the child forced down into it, the body of the uterus steadily retracting. Retraction ring mounts higher and higher, the groove being visible and palpable externally.	5. Contraction ring remains at one level. Position of child unaltered. No groove visible or palpable externally.
6. Presenting part high up, fixed.	6. Presenting part high up, unfixed.
7. No advance of presenting part.	7. Advances with each pain and recedes again at once.
8. General condition poor. Face anxious, pale, sordes round lips, rapid pulse, exhaustion.	8. General condition good for some hours, colour good, pulse good, no sordes. Frantic with unavailing pain.

As regards No. 4 my case differs from the majority of those recorded in these points: that the contractions were very powerful and for a time tonic, and that the uterus was very

tender. Records of other cases state that the uterus has, as a rule, been in a state of inertia and there has been no tenderness. Galabin in 1897 described the spasm in hour-glass uterus in the third stage as analogous to rigid cervix of the first stage, and says that it is always associated with absence of active expulsive pains.

It is possible, then, that there are these two types of spasmodic stricture:

1. Associated with uterine inertia and caused by local irritation; due in part to early rupture of the membranes and manipulations; uterus not tender.
2. Associated with powerful tonic uterine contractions, cause unknown; presumably due to some inherent irritability of the uterine muscle; uterus very tender.

As regards No. 5 there has been some discussion. Clifford White has queried the first entry, saying that neither he nor some of his colleagues had ever felt Bandl's ring per abdomen in a case of obstructed labour. On the other hand, some writers when reporting cases of dyslocia due to contraction ring have stated that the ring was externally palpable.

Diagram 1 shows the outline of a uterus during the second stage in normal labour, the three constrictions being, of course the upper limit of the lower uterine segment, the internal os, and the external os.

Diagram 2 shows the outline of a uterus during the second stage in obstructed labour with threatened rupture. The vagina, cervix and lower uterine segment are all stretched up and ballooned out to receive a large portion of the foetus. The upper segment has retracted and the retraction or Bandl's ring is well marked.

DIAGRAM 1.

DIAGRAM 2.

DIAGRAM 3.

Diagram 3 shows a uterus during the second stage in a case of spasmodic stricture. The vagina is normal, the free edge of the cervix hangs loose and flaccid, there is no distension or ballooning of any part. In my case the head lay in the lower uterine segment and the upper part of the cervix, firmly held by the neck. The outline of the uterus remained ovoid to palpation and inspection.

I am aware that these diagrams may appear exaggerated, particularly to anyone who has seen the illustrations of those cases in which the uterus was removed entire and afterwards frozen and sectioned. What remained of the contraction ring is seen as a ridge in the uterine wall, so slight that one cannot imagine it to have caused obstruction. This diagram shows the impression conveyed to my mind at the time of intrauterine examination.

Treatment.

It is universally acknowledged that the correct treatment of hour-glass uterus in the third stage of labour, uncomplicated by haemorrhage, is morphine and rest. By analogy, one would suppose that many cases occurring earlier in labour will yield to such treatment, and doubtless this is true, many of such cases passing unrecognized. But there are other cases in which the spasm will not relax under any expectant treatment. A case has been reported which was watched for thirty-six hours without relaxation. Willett has reported a case which only yielded to continuous traction applied for three hours after craniotomy.

Great anxiety attends any intrauterine operation, on behalf both of the child and the mother. Wilhelm, of Missouri, reported six cases treated by manual dilatation. In five of these he turned the child and extracted by the breech. All the children were stillborn. In the sixth case he applied forceps after manual dilatation and extracted the child alive. He states, as a result of this experience, that the foetal mortality is very high, but there is little danger to the mother in manual dilatation and delivery. In this opinion I cannot concur, nor do I find it corroborated by other authorities. I agree rather with Hedley, who says that manual dilatation carries the threefold danger of rupture, shock, and sepsis. There are records of deaths from these causes following manual dilatation. De Lee's opinion is that a uterus in localized or general tetanus will not rupture spontaneously,

but there is considerable danger of tearing the uterus by operation during the spasm.

Incision of the ring per vaginam is too dangerous to be attempted. Version is absolutely contraindicated; it is, moreover, often impossible.

The application of forceps is very rarely helpful. Where the ring is around the child's neck the blades almost invariably slip. If they do succeed in dragging the head down to the vulva it simply carries the ring down with it, unless the latter has been torn in the process. A case has been reported where the ring had formed around the shoulders of the second of twins, and where very gradual traction with forceps caused a tear of the vagina, cervix, and lower uterine segment into the broad ligament. The application of forceps, therefore, is not advisable in the case of a living child. Where the child is dead forceps with cleidotomy and steady traction will doubtless be sometimes successful.

Craniotomy also has but a limited field, even within that class where the child is already dead. Embryotomy has succeeded in a few cases, in others it has been impossible to deliver even after evisceration.

There is no doubt that where the child is dead the ring in the majority of cases will yield to slight steady traction if that part of the foetus endeavouring to enter the ring be coneshaped. Division of the clavicles will therefore be of use where the shoulders are obstructed. Again, in that case of breech presentation reported by Lady Barrett to which I have already referred, a hydrocephalic head was successfully extracted through the ring after puncture of the spinal canal.

There remains but Caesarean section. Mr. Munro Kerr has said very recently that probably Caesarean section will in future be more frequently performed for the relief of this condition. And it surely is the ideal treatment for obstinate cases if only the uterus be not already infected. Where infection has already occurred the section should be followed by hysterectomy, or, if the child be dead, a hysterectomy alone is indicated.

With regard to treatment I am impressed by the following facts:

1. The difficulty, danger, and high mortality attending active interference.
2. That the only abnormal condition is a localized spasm of the uterine muscle.
3. That deep anaesthesia diminishes muscular spasm.
4. That repeated examinations increase spasm and are therefore contraindicated.
5. That in the case I have reported deep and prolonged anaesthesia alone resulted in the spontaneous delivery of a healthy child.
6. That in the previous confinements of this patient forceps were applied on every occasion, with an infant mortality of 50 per cent.

As a result I consider that the correct treatment for this condition is *deep anaesthesia, if necessary prolonged, and nothing else*. This treatment will, I believe, very nearly eliminate the necessity for Caesarean section.

RECTAL ADMINISTRATION OF TARTARATED ANTIMONY IN BILHARZIASIS.

BY

H. F. WILSON, M.C., M.B., B.CH.,

DAVID GORDON MEMORIAL HOSPITAL, LIVINGSTONIA, NYASALAND.

ALTHOUGH a number of papers have appeared recently on the treatment of *Schistoma haematobium* by tartar emetic, the method invariably advocated has been intravenous injection. For any parasitic infection of the general circulation this could hardly be improved upon, as the drug enters the blood stream in such quantities and at such precise times as the introducer desires. But where it is desired to destroy a parasite whose habitat does not generally extend beyond the portal circulation it seems more reasonable to introduce the

parasiticide directly into the radicals of that system, so that it may meet with what it is intended to kill in greater concentration than if injected into a superficial vein and accordingly distributed to all parts of the body before reaching its object.

As, however, accessible veins of the portal circulation are not available for injection, we are thrown back upon the absorbing powers of the rectal mucous membrane, reached by solutions of the tartarated antimony given as small enemas. The drug absorbed in this way enters the superior haemorrhoidal vein, where, in cases with rectal symptoms, the worms are understood to lay their eggs.¹ The free intercommunication between this vein and the vesical plexus allows of the drug passing to the bladder wall, in which oviposition is the rule in cases with haematuria or other vesical symptoms. That part of the dose which does not find its way into the vesical veins passes up to the portal vein itself, where the pairing of the worms takes place, and so reaches the liver, where the younger immature forms are found, and in this way exerts its maximum action upon all stages of the creature's life cycle before being merged into the general circulation, in which worms are only found, Kartulis tells us, in the inferior vena cava; this is the first part to be reached by the antimony.

Whether the portal system can be "sterilized" by the administration of a few large doses in this way, and the treatment reduced to, at most, one or two administrations, must be left for further investigation. The purpose of this preliminary note is to draw attention to the tolerance of the rectum to what would be considered very large doses if given in any other way, and in particular to emphasize the convenience of this method where the personal idiosyncrasy of the patient, or, in women and children, the difficulty of locating and entering a vein, makes the intravenous method undesirable.

Indeed, as an alternative it must always be of practical value to practitioners who, for whatever reason, do not go in for intravenous work, or who find the necessary sterilization of solutions, needles, etc., an undesirable call upon their time, apart from the need for giving an intravenous injection personally. Finally, experience of the high lying plateaux of Central Africa goes to show that, both in the rains and in the cold season which succeeds them, many days are most unsuitable for finding veins in the subcutaneous tissues of naked and shivering patients; at times weeks have passed without days sunny enough to give what may be called "good veins." At such times, when many cases of bilharziasis are waiting treatment, the method advocated here is a real boon.

Four cases only will be cited to illustrate the possibilities of intrarectal treatment.

CASE I.—Child with Old-standing Bilharzia Infection of the Bladder Cured after Fourteen Intrarectal Injections.

John, a half-caste boy aged about 7, who had come up country from Southern Rhodesia eighteen months before, complained of suprapubic pain and of passing blood at the end of micturition; these symptoms were of some four or five months' duration. There was a history of a streak of blood in the stool, which had defied treatment for some time, but at that time no search seems to have been made for schistosome eggs in the faeces. Examination of uncentrifuged specimen of urine revealed terminal spined ova in astonishing numbers; the specimen was red and loaded with urates. No eggs were found in faeces. Treatment was commenced with an injection of 1 grain in 100 c.cm. of water at body temperature. A few drops of tincture of opium were added, but as there was no intolerance this was not repeated. Two days later a dose of 2 grains was given in the same way, and thereafter for three weeks the drug was given every second day in gradually increasing doses—2 grains, 3 grains, 4 grains, 5 grains, etc. During the first week the urine cleared of blood, but after eleven doses a few shrivelled eggs were still to be seen. The 12-grain dose was repeated twice, and two days later 14 grains were given, after which no sign of an egg was found on examining the last part of a specimen passed in the morning on rising and centrifugizing the sediment after some hours' standing. At no time in the course of treatment did the boy show any sign of nausea, nor were his appetite or spirits in any way affected. He received in all 104 grains.

CASE II.—Child with Enlargement of Liver, Ascites and Anaemia: Schistosome Ova in Faeces: Cured after Fourteen Injections.

Simiyon, a boy of perhaps 6, was brought in with a much-distended belly, containing a quantity of free fluid; the liver was two fingerbreadths below the costal margin. The boy was anaemic and listless. Examination of the faeces showed numbers of ova, chiefly lateral-spined in type. He was treated *pari passu* with Case I, in the same doses up to 12 grains; this was then followed by one of 16 grains. No eggs were found thereafter; the abdomen had decreased in size so as to be no larger than that of the run of native children of his age, and although the liver was still easily palpable

the free fluid had disappeared. Under tonics the anaemia improved, and he was dismissed after six weeks a totally different boy, having received in all 108 grains without showing any tendency to nausea or vomiting.

CASE III.—Lad with Haematuria Cured in Eight Attendances.

Naaman, an apprentice carpenter, aged about 17, complained of passing blood in the urine for the previous month or two. The urine was smoky, and on centrifugalization showed ova of bilharzia. He came every other day for three weeks, receiving doses of 2 grains, 4 grains, 6 grains, etc. The urine cleared after the third injection, and by the time that he had received eight doses, amounting in all to 68 grains, the urine was found to be free of ova. He spent his midday rest hour receiving the injection and lying down, but otherwise was not away from his ordinary work.

CASE IV.—Old Man with Pronounced Haematuria Cured after Four Injections Administered in Five Days.

This old man could give no history of his complaint, but the urine was of a thick port-wine appearance with a sediment of urates. Ova were found easily. The first dose was 5 grains; this was followed two days later by a dose of 8 grains; the urine was then amber in colour without a trace of blood. On the next two days he received successively 10 grains and 12 grains; treatment was then discontinued as the centrifugalized specimens of urine examined contained no more ova. He had been given 35 grains in the five days without showing any symptom of intolerance.

The treatment was in all these cases carried out in the following manner: The bowels were caused to move daily in the morning by giving if needed a mild laxative at night. Some three hours afterwards the patient lay down upon his left side, and the dose, made up to about one or two ounces by the addition of warm water, was administered by the hospital orderly by means of a funnel attached to a No. 12 rubber worm catheter, which after being lubricated was passed well up into the rectum; it is advisable to compress it firmly between the finger and thumb as it is being withdrawn so that the whole of the solution be introduced. The patient has been directed to lie down for a couple of hours, but whether this is essential has not been finally settled. In some cases the bowel must be cleared first by a soap and water enema, but this is not the rule by any means.

Conclusions.

1. The results of intrarectal administration of tartarated antimony are in no way inferior to intravenous.
2. It economizes time, and is free from all risk.
3. Nausea and vomiting occur less frequently than when the drug is run into the general circulation.
4. Case IV suggests the possibility of reducing the number of attendances for treatment considerably.

SOME FUNCTIONS OF THE SUPRARENAL GLANDS.

BY
EVELYN E. HEWER,

LECTURER IN HISTOLOGY AND ASSISTANT LECTURER IN PHYSIOLOGY
AT THE LONDON (ROYAL FREE HOSPITAL) SCHOOL OF
MEDICINE FOR WOMEN.

The medullary portion of the suprarenal gland (derived, with the cells of the sympathetic ganglia, from the neuroblasts of the central nervous system) is well known to be concerned with the elaboration of an internal secretion which contains as one of its active principles the substance known as adrenaline; but the part played in the animal economy by the cortex (developed from the mesothelium of the genital ridge) is still obscure. In view of the vital importance of this organ some experimental results recently obtained in rats seem to be worth recording. Even though there is no evidence that the suprarenal gland of rats is functionally homologous with that of man, yet there is no evidence to the contrary, and some of the findings are most suggestive.

The experiments consisted of feeding or inoculating white rats of varying ages with different preparations of suprarenal cortex for varying periods, and then killing, and examining various organs histologically. The preparations used were as follows, and I am much indebted to these firms for their courtesy and assistance in obtaining these preparations:

1. Adcortogen (by Carnrick Co.), which was dried cortex, and contained some adrenaline.
2. Cortex lipoids (by British Organotherapy Co.), which was a liquid extract containing only the lipoids.
3. Cortex extract B (by Carnrick Co.), which was a watery extract of cortex, containing no lipoids but some adrenaline.

4. Cortex extract C (by Carnrick Co.), which was the same as B, but free from adrenaline.

5. Adrenaline (by Parke, Davis). This was used to obtain control animals for those treated with cortical preparations which were found to contain adrenaline.

In all, 118 animals were used, and the following are the most striking of the results obtained. It is not proposed to give here all the details of the experiments, as it is hoped that the work will be published in full elsewhere.

The general health of the animals was not affected, except rarely when using adrenaline-containing extracts. But an extraordinary formation and deposition of fat was obtained in most of the animals, thus confirming the observations of others that the suprarenal cortex plays a part in controlling the fat metabolism of the body, which may thus become perverted in hyperactivity of the gland. In addition, nearly all the rats developed a curious condition of the coat; the fur was thick, fine and glossy (as it should be in health), but came out very freely on handling; the hair follicles microscopically showed degeneration. This condition was not due to the adrenaline, and, points to a connexion between suprarenal cortex and calcium metabolism, as perversion of the latter is known to give rise to nutritional disturbances of the skin.

The organs to which attention was directed more particularly were those of internal secretion, and the following are the most conspicuous of the results obtained.

Thymus.—The gland was obviously affected by the treatment. There was most marked increase of invading mast cells; some of these cells are apparently always present in this animal, but the significance of this great increase is not clear. The gland was apparently responding to stimulation in the direction of involution, as indicated by an increase in the Hassall's corpuscles and chromophobe complexes, normally so scanty in the rat. In many cases, also, there were present large clear eosinophil cells of endothelial type invading the gland by the lymph channels, and sometimes completely destroying the normal structure. The appearance of these cells, both here and in the haemolymph glands, can hardly be a specific effect of the treatment, but probably indicates some degree of lowered resistance, the lymph glands being the organs first attacked.

Pancreas.—The gland appeared normal, but two points of interest may be mentioned. First, in the series where adrenaline was being given, a definite thickening of blood vessel walls, both here and in the spleen, was frequently found; secondly, lymphocytes were usually present in the islets. This lymphocyte increase was not confined to the pancreas, but was found in many organs, and is interesting in view of the increase commonly found in Addison's disease. The suprarenal gland, as a whole, appears to stimulate the appearance of lymphocytes in the tissues (no blood counts were made); perhaps there may be some connexion between the sexual immaturity of status lymphaticus and the influence exerted by the suprarenal cortex on the gonads.

Spleen.—Generalized lymphocytic increase was well shown, and the vascularity and blood pigments were very constantly increased. Adrenaline appears to affect the organ adversely; the capillaries were found engorged with blood, lymphocytes were frequently found below the endothelium of the blood vessels, and the typical structure was lost. Increase of giant cells was frequently observed, but no evidence of tuberculous infection.

Male Gonads.—The treatment at first hastened the genital development, but, when continued for some time, in every case degeneration of the seminiferous tubules occurred. The breakdown was very marked, but after a long interval some repair was usually found. The interstitial tissue was also affected, the lipid constituent causing a cellular decrease and the non-lipoid constituents an increase; in this way a balance may be kept by the full action of the gland. The interstitial tissue contained a large quantity of eosinophil exudate in nearly every case.

Female Gonads.—Sexual precocity in the female rat is difficult to determine experimentally. Degeneration of the older follicles was always found; the younger follicles appeared normal, and therefore were either more resistant to treatment or had undergone repair. The interstitial cells were constantly increased.

Suprarenals.—Evidence was obtained that normally cells atrophy at the medullary border, and that regeneration occurs from the zona glomerulosa; this change was found to be accelerated in pregnancy, and could be stimulated by treatment with cortical preparations more easily in the female.

than in the male. Acute degeneration of the whole gland followed inoculation with the non-lipoid cortical constituents, together with adrenaline.

Thyroid.—The gland was apparently stimulated by the cortex, but adrenaline over-stimulated it to the point of exhaustion.

Haemolymph Glands.—The most striking change observed was in the pigment. Three types could be distinguished. First, the yellow-brown amorphous pigment due to breakdown of haemoglobin; this was always increased, showing that the suprarenal stimulates blood destruction. Secondly, bright yellow pigment in fatty droplets, probably representing some of the inoculated lipid material laid down in altered form in these glands. Thirdly, brown pigment found in special cells of varying size and shape in varying amounts; these are melanoblast cells, and were found most frequently in the haemolymph glands, occasionally in the true lymph glands, and rarely in almost any situation, distributed by the lymph channels. The suggestive point about these cells is that they were only found when the preparation contained adrenaline, and never under any other conditions. Excessive or perverted activity of the suprarenal medulla, therefore, may be directly responsible for the pigment formation of Addison's disease and may also play a part in the formation of pigmented tumours.

Conclusions.

Although it is not possible to apply results obtained with certain animals to another species, nor possible always to distinguish between glandular hyperactivity and perverted activity, nor between purely structural hyperplasia and functional hyperplasia, yet the following conclusions seem worthy of record:

1. The suprarenal cortex plays a part in fat metabolism and in calcium metabolism.

2. The suprarenal cortex stimulates the thymus to involution.

3. The suprarenal cortex controls the gonads in both male and female with respect to both reproductive and interstitial cells.

4. The suprarenal gland acts as a whole in controlling general health, in controlling haemoglobin breakdown, in regulating the production of lymphocytes, in regulating the production of mast cells, and in stimulating the thyroid.

5. The suprarenal medulla is connected with the formation of melanoblast cells.

6. Inoculation with various suprarenal extracts appears to lower the resistance of experimental animals, as is indicated by the condition of the lymph and haemolymph glands.

I should like to thank Professor Cullis for her continued interest and helpful criticism throughout this work. The expenses of this research are being defrayed by a grant from the Royal Society.

THE VIRULENCE OF DIPHTHERIA-LIKE ORGANISMS.

(Further Note.)

BY

A. J. EAGLETON, M.D. LOND., M.R.C.P. LOND.,

AND

E. M. BAXTER, M.Sc. SHEFFIELD.

(From the Wellcome Physiological Research Laboratories.)

THE bacteriological diagnosis of diphtheria, though based generally on the morphology and cultural characteristics of the *Bacillus diphtheriae*, must depend ultimately on the animal test, whereby the pathogenicity of the infecting organism can be definitely established. While the animal test is advisable, even in clinical work, as a periodical check on the routine methods of diagnosis, in dealing with the carrier problem and prevention of diphtheria it is indispensable. The time may come when some other test may replace it; this is, however, very improbable.

By the intracutaneous method (Eagleton and Baxter, 1921) a large number of pathogenicity tests can be carried out speedily and economically. Further experience of this method has served to confirm our belief in its reliability, evidence of which is given in the second part of this paper. The first section deals with 161 cultures of diphtheria-like organisms, all of which were tested for pathogenicity, and the majority for fermentative power. Slopes of Loeffler's

serum medium were employed for primary cultures, and plates of the same medium for subsequent purification.

The intracutaneous method was used for testing pathogenicity, checked frequently, especially when the findings were negative, by subcutaneous injections, as will be described later.

I. EXAMINATION OF CULTURES.

The cultures were derived from three sources, and each group will be considered separately.

(a) Thirty-seven cultures from cases of clinical diphtheria gave the following results:

Morphology.	Glucose.	Saccharose.	Virulence.
<i>B. diphtheriae</i> ...	Acid	Negative	+ 33
<i>B. diphtheriae</i> ...	Not done	Not done	+ 3
Hoffmann's bacillus ...	Not done	Not done	- 1
			37

Of the 33 virulent cultures of *B. diphtheriae* the "sugar" reactions of which were tested, 2 fermented saccharose as well as glucose. These cultures, after plating, had been maintained on Loeffler medium for over ten weeks, and were seemingly pure, judging by smear preparations and appearance of growth. On replating, however, a very slight contamination was found—in one case a coccus and in the other a Gram-positive bacillus which produced acid in saccharose. When freed from these impurities the two strains failed to ferment saccharose.

(b) A single throat swab was taken from 112 patients who had had diphtheria and had completely recovered at the time of examination. Nineteen strains of *B. diphtheriae* and Hoffmann's bacillus were obtained, and gave the following results:

Morphology.	Glucose.	Saccharose.	Virulence.
<i>B. diphtheriae</i> ...	Acid	Negative	+ 9
<i>B. diphtheriae</i> ...	Not done	Not done	+ 1
<i>B. diphtheriae</i> ...	Acid	Negative	- 1
Hoffmann's bacillus ...	Negative	Negative	- 5
Hoffmann's bacillus ...	Not done	Not done	- 3
			19

Five of the nine virulent strains, when first tested in sugars, produced acid in saccharose; this was, however, due to a very slight degree of contamination. The fermentation of saccharose in these cases was generally slight, and might not take place till after the third day of incubation.

The most difficult contamination to eliminate is a Gram-positive sporing bacillus, which may lie dormant for weeks in a culture on solid medium. This organism ferments glucose and saccharose, and, when abundant or in pure culture, liquefies Loeffler medium.

(c) Comprises 105 cultures from 67 carriers, none of whom had had diphtheria, but most of whom had been in contact with a case. The results found in this group were as follows:

Morphology.	Glucose.	Saccharose.	Virulence.
<i>B. diphtheriae</i> ...	Acid	Negative	+ 30
<i>B. diphtheriae</i> ...	Not done	Not done	+ 3
<i>B. diphtheriae</i> ...	Acid	Negative	- 52
<i>B. diphtheriae</i> ...	Acid	Acid	- 8
<i>B. diphtheriae</i> ...	Not done	Not done	- 1
Hoffmann's bacillus ...	Negative	Negative	- 11
			105

Of the 39 virulent cultures, one produced acid in saccharose, but as with similar cases in the other groups, a very slight contamination was found to be responsible.

When we compare these three groups we notice that in Group A only one culture was avirulent and that was Hoffmann's bacillus. All the remainder were virulent, and, except for three not tested, gave typical "sugar" reactions. In Group B we find 10 virulent and one avirulent *B. diphtheriae*, the remainder being Hoffmann's bacillus; whereas in Group C, of 94 bacilli morphologically resembling *B. diphtheriae*, only 33 were virulent; excluding the eight strains which fermented saccharose (*B. xerosis*) and the one avirulent

strain, the "sugar" reactions of which were not tested, we find 33 virulent and 52 avirulent.

Of the cultures of *B. diphtheriae* from clinical cases we find 100 per cent. virulent; of those from convalescents 90.9 per cent.; while of the cultures from carriers which were typical on morphology and "sugar" reactions we find only 38.8 per cent. virulent.

These results agree with the findings of most other workers in so far as they show that avirulent strains are rarely found except in people who have never, or at all events not recently, suffered from diphtheria (Graham Smith, 1908, Arkwright, 1912).

Fermentation Reactions.—Of the 161 cultures in the three groups the sugar reactions were tested in all except twelve instances. We used as a routine only glucose and saccharose. Thirty strains were also examined for action on dextrin, salicin, and litmus milk. We found, however, that by using glucose and saccharose alone we obtained as much information as we could from the more extended set of reagents. All the virulent *B. diphtheriae* which we have tested hitherto produce acid in glucose but not in saccharose. The same reaction was, however, given by 53 out of 61 avirulent cultures, though the amount of acid produced by two of them was very slight. We have not so far met with a virulent strain which, when absolutely pure, produces acid in saccharose. Graham Smith (1908) has reported several from one epidemic. Our difficulties in getting rid of contamination by saccharose-fermenting organisms have been noticed. We succeeded only by repeated plating, and in more than one instance after picking off several colonies from the same plate and testing the sugar reactions of each, we found that some of the "single" colonies failed to ferment saccharose, whilst others did so.

We have so far found no evidence that a culture may "lose its virulence" on being kept. It need only be mentioned that smears must be made from every culture before it is used for inoculating animals. One culture in our series appeared to be a pure culture of Hoffmann's bacillus and was avirulent by intracutaneous test. Two months later, when examined for morphology, sugar reactions and virulence, it was found to be indistinguishable from *B. diphtheriae* on morphology and "sugar" reactions, and to be virulent. The culture was plated, and from the plate a number of colonies were picked off. Some proved to be pure cultures of Hoffmann's bacillus, others *B. diphtheriae*. Hoffmann's bacillus and *B. diphtheriae* may therefore live in the same tube for months and neither be destroyed. A culture originally avirulent may, when next examined, be found virulent because the *B. diphtheriae* are in enormous excess, and vice versa.

II. RELIABILITY OF INTRACUTANEOUS TEST.

We have compared the results of determination of virulence by the intracutaneous method with those obtained by the methods hitherto mostly used—that is, the subcutaneous injection of a forty-eight hour broth culture or of the growth from a Loeffler slope.

We chose for comparative testing by the subcutaneous method 83 cultures which had been tested and classified by the intracutaneous method; of these, 57 were avirulent and 26 virulent. All these cultures were subsequently tested by the subcutaneous injection into guinea-pigs of either an emulsion of the whole growth on an eighteen-hour Loeffler slope culture or of 2 c.cm. of a forty-eight or ninety-six-hour broth culture. Twenty-one of the cultures were tested in two ways by the subcutaneous method, the emulsion of a Loeffler slope culture and 2 c.cm. of a forty-eight or ninety-six-hour broth culture being injected subcutaneously into separate guinea-pigs.

As a control a known virulent culture, a Park 8 strain, was used throughout. A small fraction of an eighteen-hour Loeffler slope culture of this organism killed, while of a forty-eight-hour broth culture 0.01 c.cm. killed; smaller doses were not tested.

The batch of broth employed was in constant use for the routine production of high grade toxin; we were, therefore, certain that the broth used in testing our cultures was one suitable for the production of toxin.

In every instance the results obtained by the intracutaneous and subcutaneous methods agreed—that is, no culture proved to be virulent by one method but avirulent by the other.

We think it may be justly claimed that this method of testing virulence is not only rapid and economical but simple and reliable.

Results of Repeated Swabbing.

We had the opportunity of examining swabs taken from seven notified "carriers" who were under observation for two to four months. Twenty-six cultures of organisms morphologically indistinguishable from *B. diphtheriae* were obtained

from these carriers and examined by the intracutaneous method. One child gave four "virulent" cultures over a period of two months. One gave a "virulent" followed by an "avirulent" culture. In one case an "avirulent" *B. diphtheriae* and a Hoffmann's bacillus were found on different dates over a period of three months. Cultures indistinguishable from *B. diphtheriae* but, when isolated, found to ferment glucose and saccharose, were repeatedly obtained from the throat swab taken from two children.

Results and Conclusions.

Of 161 strains cultivated from cases of diphtheria, convalescents and carriers, 79 were virulent *B. diphtheriae*, 62 were avirulent *B. diphtheriae* (including 8 *B. zersosis*), and 20 were Hoffmann's bacillus (all avirulent).

Cultures of *B. diphtheriae* from cases of diphtheria were virulent in 100 per cent. of those examined; from convalescents in 90.9 per cent.; from carriers in only 38.8 per cent.

Sugar reactions were carried out with 149 cultures; glucose and saccharose were the only reagents used as a routine. The value of "sugar" tests may be summed up as follows:

If glucose is not fermented, the culture is not virulent *B. diphtheriae*.

If glucose is fermented but not saccharose, the organism may be virulent or may not.

If both glucose and saccharose are fermented, the organism may be *B. zersosis*, may be contaminated, or (Graham Smith) may be virulent.

We have found no evidence that virulent cultures, if isolated in a pure condition, become avirulent.

For absolute diagnosis, a culture morphologically resembling *B. diphtheriae* and capable of producing acid in glucose must be submitted to a virulence test.

The intracutaneous method is simple, economical, and apparently reliable.

Our thanks are due to those who have provided us with material for this research, especially Dr. F. Foord Caiger and Dr. Graham Forbes. Without the help of Dr. Okell and our other colleagues and the guidance of Dr. O'Brien, our work would have been still less complete than we have left it. Finally, to Mr. Tottem and the rest of the laboratory staff we hereby offer acknowledgement of their large share in whatever success we may have obtained.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

AN EMERGENCY METHOD IN PRESBYOPIA AND HYPERMETROPIA.

THE following cases are recorded as examples of the use of the stenopaic disc in presbyopia and hypermetropia:

Case 1.—Aged 58. Vision: R. = J. 6; L. = J. 6. With disc, R. = J. 1; L. = J. 1.

Case 2.—Aged 61. Hypermetropic, wearing for distance + 4.5 D. sphere in each eye. Vision: R. = 5/60; L. = 4/60. With distant glasses, R. = 6/12; L. = 6/12 partly. With disc only, R. = 6/9 partly; L. = 6/12 partly. Without disc, R. = J. 18; L. = J. 16. With disc only, R. = J. 10; L. = J. 6. With disc and correcting lens for distance, R. = J. 1; L. = J. 1. Retinoscopy revealed astigmatism in the left eye.

Case 3.—Aged 47. Vision: R. = 6/6 H.M., with + 1.0 D. sphere, R. = 6/6; L. = 6/6 H.M., with + 1.0 D. sphere, L. = 6/6. Without disc, R. = J. 2 with some difficulty; L. = J. 2 with some difficulty. With disc only, R. = J. 1; L. = J. 1.

We have thus a simple substitute, in emergency, for the reading glasses of presbyopes.

The presbyope, even an early presbyope, without the suitable lens, is in a most helpless condition when trying to decipher the small print of a telephone directory, time table, newspaper, exhibition catalogue, etc. This small print is easily, though slowly, read by means of an improvised stenopaic disc, which can quickly be made with a piece of paper or cardboard, through which a hole 1 to 2 mm. in diameter is pierced by a pin, the point of a pencil, or knife. Such an emergency measure would be of real benefit to the presbyope, stranded without reading glasses, specially in the country or on a railway journey. A hole, about the same size, through a piece of bread forms an excellent emergency substitute for a convex lens! The tunnel formed by the fingers and palm of a partially closed fist acts in the same way.

The reading distance is also much decreased. Case 3 could read J. 1 at 16 cm. with a disc; J. 2 at 29 cm. without a disc.

For distant vision in hypermetropia this emergency method would probably not be of so much practical use, though, as shown in Case 2, the distant vision is much improved.

AGNES ESTCOURT-OSWALD, M.B., D.P.H.,
Clinical Assistant, Royal London Ophthalmic Hospital.

A CASE OF FULL TERM ECTOPIC GESTATION WITH LIVING FOETUS.

I THINK there are few cases on record in which a living foetus at full term has been extracted from an ectopic sac, as in the following case:

A woman, aged 30, married nine years, who had had one full-term child eight years ago, gave a history of pelvic pain when she had missed two periods, and there was also a small amount of loss of blood per vaginam. She took no notice of this, and did not complain of anything until she had missed six periods, when she suffered from partial retention of urine. Rest and catheterization on one or two occasions soon resulted in the normal passage of urine. At this time there was a soft swelling in the middle line extending a little above the umbilicus. This seemed to be an intrauterine pregnancy. Behind the uterus was an ill-defined swelling, which was thought to be an adherent fibroid or ovarian tumour. With this diagnosis the patient was allowed to go to term with a view to Caesarean section.

At term the abdomen showed a soft, uniform swelling which was in no way different from a normal intrauterine pregnancy at term. The foetal parts could be felt, and the heart was heard beating strongly in the left iliac fossa. What appeared to be the foetal head was fixed and well down in the pelvic cavity. On vaginal examination there was a hard fixed mass lying low in Douglas's pouch with the cervix high up in front. As this appeared to be the foetal head and no other tumour could be made out I thought we had to deal with an ectopic gestation and not with an intrauterine pregnancy with a tumour behind. I decided to open the abdomen and attempt to extract a living foetus.

On opening the abdomen a soft surface, like an ordinary pregnant uterus, was found, but while there was plenty of room in front, above, and to each side, the large and small intestine were firmly adherent. I decided to go through the anterior wall of the sac, and at once found that the incision had gone through a very thinned-out anterior wall of the uterus, which covered and was implanted into the anterior wall of the sac. There was no other way to the foetus except through the posterior wall of the uterus. This was cut through and the placenta found lying in front of the baby. The baby was delivered quickly and the placenta, which was very adherent to the sac, was removed piece by piece. At this stage the haemorrhage was most alarming. The cut edges of the anterior uterine wall, which formed the anterior wall of the sac, were quickly saturated to the lower part of the abdominal incision and the sac was packed firmly with gauze strips. This controlled the haemorrhage.

The patient, after a somewhat stormy convalescence, made a good recovery. The baby, pink and healthy, weighed 7 lb.; its trunk was well formed; the head was avulso-shaped from prolonged pressure and both lower limbs were greatly deformed. There was no liquor amnii in the sac of the ectopic gestation. The baby died about thirty hours after delivery.

My experience in this case has led to the following conclusions:

1. The diagnosis between an intrauterine pregnancy complicated with a tumour and an ectopic gestation at term is often very difficult, and such cases are rarely seen at this stage.

2. If diagnosed, the question of saving the foetal life should be neglected. The foetus will most likely be deformed, and the haemorrhage from the living ectopic placenta is extremely alarming.

3. The patient should therefore be allowed to go through the spasmodic labour (when the foetus dies), and the operation should take place about three weeks later, when the dangers of haemorrhage will be much less.

As far as could be ascertained, the ectopic pregnancy had begun in the left tube, and the slight bleeding from the uterus in the early history of the pregnancy no doubt denoted a threatened rupture.

H. T. HICKS, F.R.C.S. Eng.,
Honorary Gynaecological Surgeon,
Derbyshire Royal Infirmary.

RESUSCITATION AFTER APPARENT DEATH.

IN view of the opinion held about the cessation of function of the brain cells after stoppage of the circulation, I beg to report the following case:

On December 7th, 1921, I performed double midline tubinectomy on an apparently healthy woman aged 38 years. The following notes are copied from her case sheet, which was entered up at once, the times and statements being the common agreement of several observers.

6.5 p.m.: The patient left the theatre in a perfectly satisfactory condition, in very light anaesthesia, as she had only been under the anaesthetic for five or six minutes, and she had had scarcely any haemorrhage. She was put to bed in the ward, and at 6.15 p.m. it was noticed that she had stopped breathing and had no pulse. I received a request in the theatre to go to the ward at once. I was just completing the succeeding operation, and went to the ward immediately it was finished.

I found the patient ashen and pulseless. There was no heart beat to be heard on auscultation. Artificial respiration had been in progress and oxygen had been administered since 6.15 p.m.; these measures were continued whilst preparations were made for heart massage.

At 6.25 p.m. an incision was made along the left costal margin; the heart was found to be stopped in diastole. Bimanual massage was applied through the diaphragm, whilst another house-surgeon applied Schaller's method of artificial respiration. The foot of the bed was raised on to chairs, the legs bandaged tightly from below upwards, hot bottles placed around the patient, and pressure applied to the splanchnic plexus. At 6.40 p.m. the heart was still inert, so 1 c.cm. of adrenaline was injected direct into the left ventricle. At 6.42 p.m. the heart began to beat. At 6.45 p.m. the radial pulse was felt, and at this point digitalis gr. 1.00 and strychnine gr. 1.60 were injected into the median basilic vein. By 7 p.m. the heart was beating strongly, but there was no respiratory effort, in spite of continuous artificial respiration and massage to the heart in order to assist its efforts, so 1 c.cm. pituitrin and 1 c.cm. adrenaline were injected into the left ventricle.

In spite of continual heart massage and artificial respiration there was at 7.25 p.m. still no effort to breathe. The pulse was good, the rate 100 a minute. As the other house-surgeon, the anaesthetist, and myself were unable to carry on any longer, two more house-surgeons took our places. At 7.50 p.m. the heart was beating strongly, but there was no respiratory effort. The house-physician and a dresser were now assisting by doing artificial respiration alternately. At 8 p.m. the patient made a voluntary inspiration, and one minute later made voluntary inspiratory and expiratory efforts. At 8.5 p.m. she was breathing well, the pulse rate was 90 to 100, respirations 24. She moved her position in the bed, rolled her head, moved her eyelids and eyes; she retched but did not vomit, and the pupillary reflexes were present. The incision was stitched up, hot saline having been run into the abdomen, and a tube placed in the left kidney pouch. At 9.10 p.m. the pulse was scarcely perceptible; 1 c.cm. pituitrin and 1 c.cm. adrenaline were given direct into the left ventricle, and also hot saline and 1 oz. brandy per rectum. A moment after the heart became weaker, and before the intra-ventricular injection was given, the breathing became more feeble, so artificial respiration was restarted. At 9.12 p.m. the patient had a good pulse and was breathing normally. At 9.20 p.m. heart and respiration both stopped at the same time. Digitalis gr. 1.00 and strychnine gr. 1.60 were given into a prominent vein over the anterior part of the left deltoid, and 1 c.cm. pituitrin and 1 c.cm. adrenaline into the left ventricle. Artificial respiration was again begun. At 9.25 p.m. 1 c.cm. ether was given into the left ventricle and continuous artificial respiration carried on. At 9.40 p.m., however, all attempts at resuscitation were reluctantly given up.

In spite of the fact that apparently the patient "lived" for 1 hour 20 minutes it will be noted that the heart was stopped for 27 minutes, so far as its own efforts were concerned, and that it was completely inert for 10 to 12 minutes before massage was begun. When further endeavour was decided to be useless the first question which arose in one's mind was whether the patient was dead all the time, and the actions which were aroused were merely on a par with a physiological experiment. I am indebted to Mr. A. L. Macleod, honorary aural surgeon to this infirmary, for permission to publish this case.

GILBERT R. A. ARMSTRONG, M.B., Ch.B. Edin.,
Late House Surgeon, Leicester Royal Infirmary.

FRACTURE OF THE TERMINAL PHALANX OF A FINGER WITH RUPTURE OF THE COMMON EXTENSOR TENDON.

THE case reported by Dr. J. N. Laird (p. 101) is interesting to me, for I had the misfortune to experience a similar injury to my right ring finger while playing football in 1913. The shot was very forceful and at close range to the goal. The chip of bone from the dorsal aspect of the base of the terminal phalanx seems to have been larger in my case. Treatment by hyperextension was tried for fourteen days, but without success.

Sir J. O. Skervington, Windsor, kindly agreed to operate. He made a horseshoe skin flap (base proximal) over the joint and took a "snick" in the dorsal tendon expansion, which was sutured with catgut. The skin was then stitched back in position. The finger was splinted for fourteen days. The result is excellent, both functionally and aesthetically. Only with difficulty can the line of incision now be demonstrated.

It may be worthy of mention that the pain experienced after operation was considerable, presumably due to effusion under the unyielding tendon. It was relieved by morphine.

London, W. CECIL BURNHAM, M.B., Ch.B., F.R.C.S.E.

Reports of Societies.

PROOF OF LIVE BIRTH IN CRIMINAL CASES.

At a meeting of the Medico-Legal Society on January 17th, the President, the Right Hon. Lord Justice ATKIN, being in the chair, Professor HARVEY LITTLEJOHN read a paper entitled the proof of live birth in criminal cases.

The crime of infanticide, he said, had from time immemorial been common, and on this account, as well as from the difficulties of proof and special circumstances associated with it, had given rise to a vast amount of literature and attracted the attention of medical jurists in all civilized countries. The chief difficulty encountered in proving infanticide arose from the fact that before the charge of causing its death could be preferred the law demanded evidence that the child had been "born alive"—that is, had had an existence when completely outside the body of its mother. In Germany and certain other countries proof of life at the time of birth only was required, since the crime consisted in causing death during or after birth, and the birth was held to have commenced whenever the presenting part became engaged in the pelvis as a result of labour pains. In this country the essential test of life demanded was the occurrence of respiration, and it was generally held that it was not possible to affirm positively that respiration—even full respiration—did not occur before complete expulsion of the child's body.

Importance of Thorough Post-Mortem Examination.

In Professor Littlejohn's opinion, however, the difficulty arising from the above-mentioned cause had been exaggerated, and this he considered was to a large extent due to faulty teaching, and to statements in the textbooks, which did not lay sufficient stress on the significance of full respiration, and unduly emphasized the fallacies said to underlie the hydrostatic test. In his opinion a careful *post-mortem* examination should, in most cases, enable a definite opinion to be given as to whether or not the child had been born alive. It was desirable, however, wherever possible, to have these *post-mortem* examinations performed only by persons with large experience in dealing with such cases. In commencing the necropsy he considered it to be a good practice to examine the head first, as this afforded an opportunity of noting the condition of the contents of the skull before the blood drained away during the examination of the trunk, and also because it enabled the appearances in the lungs to be better interpreted when they came to be examined. It was specially important to note the presence of injuries such as fractures of the skull, the site and extent of the caput succedaneum, the amount of head moulding, and the presence of intermeningeal haemorrhage. Many infants, even of ordinary development, whose mothers had normal pelvices, suffered from very considerable compression of the head during birth, with the result that they were born dead. From such observations we might, even in an infant which showed evidence of air in its lungs, be able to affirm the extreme likelihood of a natural cause of death during or immediately after birth. The air passages should next be examined, the mouth being explored for any obstruction or wounds, such as might be produced by the insertion of the fingers into it. The tongue, together with the pharynx, should be carefully dissected out and the entrance to the larynx exposed to view. Great care must be taken in doing this not to interfere with any mass of mucus or other foreign matter which might be resting over the entrance to the larynx. One of the most frequent causes of death during birth was the accidental obstruction of the air passages by mucus sucked into the mouth during labour owing to premature efforts at respiration. The windpipe was next ligatured about halfway between the larynx and bifurcation of the trachea and divided: the contents of the thorax were then removed *en masse* after placing a ligature around the oesophagus immediately above the diaphragm. Next the lungs were examined as to physical condition, volume, crepitation, colour, marbling of surface, and, above all, for the presence of the fine mosaic of expanded air vesicles on the surface, which was absolutely characteristic of the presence of air either respired or artificially introduced. The trachea and bronchi were examined by the naked eye for foreign matter, and some of the contents were submitted to microscopic examination. The presence of blood, lanugo hairs, meconium, p-

vernix caseosa, indicated respiratory action during birth, and might supply a satisfactory cause of death. The hydrostatic test should be performed, but it merely confirmed the conclusion which any experienced examiner would have already drawn from his observations. Valuable corroboration of respiration was afforded by the presence of air in the stomach and intestines. Observations tended to show that the longer an infant lived the further the air extended down the intestines, and air in the duodenum and intestines was not only confirmation of respiration but also of the respiration having lasted for some time. If air were insufflated into the lungs of a dead child some entered the stomach but did not pass into the duodenum.

Possible Fallacies in Interpreting Appearances in the Lungs.

Two fallacies were frequently mentioned as attending the interpretation of the appearances in the lungs: (1) That the lungs might have been artificially inflated; (2) that putrefaction might be the cause of the condition. With reference to artificial inflation, while this was a valid object in a general sense, it had no importance in criminal cases in which births took place in secret and unassisted, because if the child was dead or stillborn, the mother was the last person to try to resuscitate it, even presuming that she knew how to do this. Even if the possibility were admitted, the *post-mortem* examination would disclose the true cause of death and prevent any miscarriage of justice occurring.

The objection that the appearances might be due to putrefaction was equally invalid in a case likely to lead to a criminal charge. The lungs of an infant, to all appearances fresh or only showing signs of early putrefaction, would emphatically not float in water from the presence of gases of putrefaction. The lungs of newly born infants which had not respired, and accordingly contained no organisms, resisted putrefaction to a greater degree than most of the other internal organs, and even when decomposition was advanced in the rest of the body the lungs were practically unaffected. The presence of early decomposition which might sometimes occur when a child had inspired decomposing matter at or after birth practically indicated respiration and consequent introduction of organisms. But in such cases no doubts could arise as to the respective parts played by respiration and putrefaction in causing flotation.

The Significance of Respiration.

Did the fact of a child having respired enable us to affirm that it was born alive? This was the great difficulty in connexion with medical evidence in cases of infanticide. The circumstances under which respiration could take place during the passage of the child into the world were (1) *vagitus uterinus*; (2) *vagitus vaginalis*; and (3) breathing after the birth of the head but while the rest of the body was still in the maternal passages. All authorities were agreed that the first two could only occur when there had been introduction of the head into the maternal passages during labour or in instrumental deliveries—that is, in assisted births, which were of course very unlikely to be the subject of criminal charges. These conditions accordingly had no importance with reference to the question under discussion. The possibility of respiration occurring after the birth of the head and before complete extrusion of the body was readily to be admitted, but Professor Littlejohn submitted that in this short period, while the chest and shoulders of the child were still firmly compressed by the maternal passages, any respiratory effort must be cramped and could lead only to incomplete expansion of the chest and to partial filling of the lungs with air. He was of opinion accordingly that full expansion of the lungs with air could only take place after the body was wholly outside the mother, and that this condition was therefore proof of "live birth." He would go further and hold that expansion of the greater part of both lungs in a healthy child entitled the observer to come to a similar conclusion. No injustice was done to the mother by such an opinion, because the cause of death always afforded a means of control. If in a child with partial expansion of the lungs there was sufficient natural cause of death, such as mucus obstructing the larynx, or intermeningeal haemorrhage and evidence of compression of the brain, then the cause of death was explained. It was the presence or absence of a natural cause of death, together with the fact that from the evidence of respiration the infant was living at the time of birth, that should guide the medical man in forming his opinion. If there were injuries to the child, and these

appeared to have been caused during labour or were consistent with attempted self-delivery, it had to be admitted that the child with only partially expanded lungs might not have been born alive, and the mother must get the benefit of the doubt. If, on the other hand, the injuries were not to be explained by an unintentional act, and there was no natural cause of death, it was surely difficult to avoid the conclusion that the child was born alive.

In conclusion, Professor Littlejohn emphasized his opinion that respiration complete or involving the greater part of both lungs was positive proof of live birth in the legal sense, and he was unable to agree with the statement in Taylor's *Principles and Practice of Medical Jurisprudence*, edited by the late Dr. F. J. Smith, that "for respiration, however complete or incomplete, to be considered proof of live birth, an eyewitness to those respirations is essential."

The paper was discussed by the President of the Society, Sir WILLIAM WILCOX, Dr. ARTHUR ROBERTSON, Dr. SPILSBURY, Dr. BRIND, and others.

RELATIONS BETWEEN VEGETABLE AND HUMAN PATHOLOGY.

At the meeting of the Royal Society of Tropical Medicine and Hygiene on January 19th Sir JAMES CANTLIE, who presided, said that the society that evening was venturing into a province which it had not touched before—namely, the comparative study of plant disease and human disease—but even a knowledge of botany had its value to the worker in tropical medicine.

Dr. E. J. BUTLER, Director of the Imperial Bureau of Mycology, then read a paper on relations between vegetable and human pathology. He said that the directions in which the older pathology might learn something from the study of certain disease phenomena in plants were to be sought in certain branches of cellular pathology, in the diseases involving changes in physiological processes, such as altered metabolism, in certain classes of parasitic and virus diseases, and in the effect of environmental conditions on the interaction of host and parasite. He spoke first of tumour formation in plants, as illustrated in the well known crown gall tumour caused by *Bacterium tumefaciens*. Most of the tumours were of the ordinary connective tissue cell type, and were the nearest approach that one could expect to get in plants to sarcomata, but in a few cases the tumour appeared to be composed mainly of epidermal elements, and these might be compared with epitheliomata. Secondary tumours frequently developed by a definite outgrowth from the primary of a tumour strand of infected cells. The organism could be isolated and cultivated.

Of the virus or contagium diseases, as plant pathologists called them, the most important was the mosaic group, so called because the most obvious symptom was the variegated effect of light and dark green patches on the leaves. These diseases were constitutional, the virus reaching all parts of the plant within a few days, three or four in the case of the mosaic of cucumber. Carriers had been found—that is to say, plants which showed no symptoms after inoculation, yet contained the infective virus in transmissible form. The disease was not usually fatal to annual plants, though death from weakness might occur. Mosaic and allied diseases of potato in England might cause a reduction of over 50 per cent. in the yield. So far as was known these virus diseases were insect-borne, chiefly by means of sucking insects. In no case had transmission by mere contact been demonstrated. The life of the virus varied from twenty-four hours (sometimes in cucumber mosaic) to a year or more (tobacco mosaic if dried). The lecturer said that there were a few vegetable pathologists who preferred the enzymic or toxic hypothesis to the parasitic explanation of these diseases, but most agreed that their study had made it necessary to assume that they were caused by ultramicroscopic living organisms.

In conclusion he dealt with the set of problems arising from geographical and seasonal distribution of certain diseases. It had been found possible to correlate the geographical distribution of a considerable group of plant diseases with the temperature and humidity reactions of the parasite and its host. In the simplest cases a single factor, like the degree of relative humidity of the air, acted by limiting the development of the parasite. The meteorological factor might also act by affecting the receptivity of the host plant. Thus, in the vine, mildew infection was dependent on the condition of the stomata through which the

parasite entered. But in many cases the action of the morphological factors on both parasite and host in their mutual relations—the host-parasite complex—had to be taken into account.

Dr. ANDREW BALFOUR raised the question of alkaloid production by certain trees, and the possibility that this might be a protective mechanism against insects. In the trees of the genus *Cinchona*, for example, quinine and other bitter alkaloids were produced, and it would be interesting to know whether plants which produced alkaloids were proof against insect-borne disease. Gum production might also have a protective action like that of the scab which formed over a wound. He believed that an organism from the gum of two species of acacia had been isolated, and on cultivation in a liquid medium containing levulose among other constituents, the organism produced at first slime and eventually gum.

Dr. BUTLER said that work had been done in France on a group of alkaloid-producing plants in order to study the effect of alkaloids such as nicotine on certain of the more common plant parasites. A great many plants did successfully resist parasitic invasion because they had an alkaloid, but whether this was a definite protective reaction one could not say. Gum production had been shown to be due to bacteria in a number of cases; but in the plum and peach of Europe a parasite had not been detected, and production seemed to be due to a degeneration of the cell wall, favoured by atmospheric influences, especially by rapid alternations of humidity and dryness. He added, in reply to another question, that among plants nothing similar to antibodies had been found.

Ear Disease in the Tropics.

Dr. SALISBURY-SHARPE read a paper on disease of the ear in relation to life in the tropics, particularly with regard to the ear tests which should be required of candidates for tropical service. The prospects of cure of ear disease in the tropics were not good in most cases, especially in those localities where the proportion of water vapour in the atmosphere was high. In the tropics persons liable to wax accumulations suffered more from this trouble than in temperate countries. Middle-ear suppuration also was more troublesome and dangerous in the tropics. One great cause of chronicity in these cases was a secondary infection from outside, and this was apt to be more complicated and virulent in the tropics than in other climates. Residents in the tropics were also liable to deafness from malaria and other fevers. True malarial deafness in its early stages was wholly or partially amenable to quinine. Malaria might also cause intermittent attacks of intense earache, a true otalgia. He had seen many cases of suppurative disease of the middle ear the origin of which was said to have been an attack of malaria, though he was sceptical as to the possibility of this disease originating *de novo* in that way. Ménière's disease might occur through considerable exposure to the hot sun. In Japanese river fever deafness was often a marked feature.

ELECTRICAL TREATMENT IN GYNAECOLOGY.

At a meeting of the Electro-Therapeutics Section of the Royal Society of Medicine on January 20th, Dr. E. P. CRIBBEBACH presiding, Dr. A. ZIMMERN, electrologist of the Salpêtrière Hospital, gave an address on electrical methods in gynaecology.

Dr. ZIMMERN said that in recent years electricity in a good many of its applications had been forsaken in favour of γ rays, and this was especially the case in gynaecology. It was true that electricity here had not the brilliance of surgery, but its general results, now tested by time, entirely justified its early claims. He knew of cases particularly in which uterine haemorrhages had been controlled by the application of the continuous current when other methods, including γ rays, had failed. In cases of fibroid the introduction into the uterus of a carbon electrode as the positive pole of the galvanic current, at an intensity of 30 to 50 milliamperes for five minutes twice a week, had resulted in the reduction or even the disappearance of the haemorrhage. In metritis, when complicated by menorrhagia or metrorrhagia, his custom again was to use the positive pole of the galvanic current, and this served a double purpose. If the haemorrhage resulted from muscular weakness the current was useful in stimulating the muscle fibres, and if the cause was ulceration the caustic effect of the carbon sound of suitable size was all to the good.

The intensity of current where caustic action was desired must be high; Apostoli used even 100 milliamperes or more, but his own experience had shown him that too high intensities caused

pain and disadvantage. The intensity he used was usually somewhere about 40 milliamperes, but he could give no exact figure, because it depended on the sensitiveness of the patient. It was a good precaution to begin with relatively weak intensities—20 milliamperes—and the principle should be to employ only that current which was what he called *utérinement tolérable*. To obtain a cauterizing action on the uterine cavity the sound must be drawn slowly down during the passage of the current, so that there was action on every part of the walls. Obstinate haemorrhage was in many cases due to a local cause, such as a submucous fibroid, and that was a matter for operation. If, however, the haemorrhage was not the predominant symptom and the metritis was not too recent, the negative current (15 to 20 milliamperes) would sometimes give excellent results, as would high frequency (the small spark of the resonator). In subacute or chronic metritis of gonorrhoeal origin he had found silver ionization of value, a silver sound being connected with the positive pole of the continuous current, and not more than 20 milliamperes given for five or ten minutes, with two sittings a week to begin with.

He regarded it as an elementary rule that the presence of acute, subacute, and purulent inflammation of the appendages was a contraindication against electricity. In such cases electricity was dangerous. If, again, pyrexia was present, or if it made its appearance after treatment had begun, electricity should be abandoned in favour of more classic methods, for this meant that a subacute salpingitis was not entirely extinguished. But when there was mere congestion of tubes and ovaries, electrical treatment was in no way to be feared.

Dr. ZIMMERN had employed electrolysis with platinum, silver, or nickel sounds to good effect in stricture of the cervix, and he claimed that this procedure was absolutely without danger in the treatment of any kind of stricture. Its object was, by making use of the resolving properties of the negative pole, to broaden and make more supple the cervical passage.

After the sound was introduced a small intensity of current, up to 6 or 10 milliamperes, was applied. In subsequent sittings sounds of larger diameter were employed, so that the narrow canal in time came to admit instruments which could not have been introduced at the first sitting. It was remarkable how easily a sound, negatively charged, might be introduced, when, without the current, the same instrument would have been quite impossible of introduction. Negative electrolysis might also be useful in amenorrhoea and in sterility. In amenorrhoea, when the case appeared very obstinate, his custom was to introduce a galvanic current of 20 milliamperes for five minutes twice or three times during the week preceding what might be presumed to be the period. This method, however, need only be resorted to in exceptional cases, and in ordinary amenorrhoea it was sufficient to apply continuous current in the vagina by means of a cotton tampon covering a carbon sound, or perhaps merely to excite the ovaries through the abdominal wall by moistened electrodes, the negative one being placed in front of each in turn, and the positive on the lower part of the back.

Dr. ZIMMERN touched, in conclusion, upon such conditions as incontinence of urine (where faradic current might give encouraging results, although the treatment required a long time and there was often relapse) and anal fissures, where he had found high frequency, with Oudin's resonator and metal electrodes, of very great use, the treatment nearly always giving him satisfaction, and surpassing in its results any of the surgical measures usually employed.

Dr. C. A. ROBINSON spoke of the value of diathermy in gonococcal infections in women. In the electrical department at St. Bartholomew's, under the superintendence of Dr. Cumberbatch, twelve cases of cervicitis and urethritis with gonorrhoea had been treated by diathermy, and in every case except one—which was an undoubted case of reinfection—a positive diagnosis had given place to a negative. One of the cases had been followed up for a year, and others for shorter periods, and the results appeared to be permanent. He believed that the lethal temperature for the gonococcus was easily attained by diathermic methods.

Dr. AGNES SAVILL gave an account of some cases of uterine haemorrhage treated by electrical ionization. She preferred not to undertake such cases until she had had an opinion from a gynaecologist. She used a zinc positive electrode, or, in very severe cases, a copper one. The drawback to copper was that it adhered so firmly to the membrane lining the womb that the current had to be reversed before the sound could be withdrawn. She had originally employed a curved sound, but found its insertion very difficult; a straight sound was easier, and the patients did not have so much pain. Lately, on Dr. ZIMMERN's suggestion, she had given larger doses than the cautious ones with which she began, and had even gone up to 30 or 40 milliamperes, and the results appeared to be obtained more quickly, though the discharge a day or two afterwards was increased.

One of her cases was a woman, aged 23, whose periods had never been regular and the discharge always diffuse. She had been bled more than once, and after each operation had had amenorrhoea, but the moment the periods restarted the diffuse bleeding recurred, and went on for months. She was brought to the speaker as a last resort to avoid hysterectomy. Copper ionization was given, and a current of 20 milliamperes applied for twenty minutes on eleven occasions. The womb then had become nearly normal in size, and the patient so much improved as to be able to earn her living.

Mrs. SAVILL described other successful cases and one failure.

Dr. SLOAN CHESLER demonstrated the apparatus she commonly employed for endocervicitis and similar conditions. She used a zinc electrode for acute cases, and a copper one for others, customarily giving 20 milliamperes for twenty minutes, and on reversing the current for three minutes there was no difficulty in withdrawing the sound. The number of treatments necessary was somewhere between six and twelve. She also exhibited an arrangement for applying faradic current in bladder conditions. The speaker referred to the value of the static wave in dysmenorrhoea and amenorrhoea; the technique of application was advantageous, especially in the case of unmarried women.

Dr. W. J. TURRELL spoke of the value of diathermy in the treatment of amenorrhoea and dysmenorrhoea. In the former condition an increased nutritional effect was desired, and therefore the current should be administered for a relatively long period and at a low intensity. In dysmenorrhoea the object was to induce relaxation of spasm, and hence a stronger current for a shorter time was indicated. It would be absurd to maintain that electrical treatment was the method of choice in all amenorrhoea, but he thought diathermy was rational in those well-known cases in which, owing to overwork, the nutritional forces had been diverted and an amenorrhoea set up.

Dr. A. LAPHORN SMITH said that many years ago, when there was a high mortality from the surgical treatment for fibroid, he adopted electrical methods and found them very successful. Out of 108 cases of fibroid tumour treated by electricity, 103 were symptomatically cured—that is to say, the principal symptom, menorrhagia, was cured in all of them—and the tumour in all cases shrank very much. With the improvements in surgical technique, which practically reduced mortality to vanishing point, he abandoned electricity in favour of operation. He did so because electricity in comparison was so slow and took up such a great amount of time. In dysmenorrhoea he had found electrical methods always satisfactory, and in amenorrhoea it was not to be doubted that the galvanic current supplied something that was lacking to the trophic nerve. He had found electricity useful also in cases of sterility.

Dr. JOHN ELLISON urged that before electrical treatment was undertaken for conditions diagnosed as endometritis and cervicitis it should be made certain that there was no malignant disease present. Malignant changes sometimes took place in fibroids, and he did not know whether electricity had any effect there, but he thought there was a certain amount of risk unless malignancy was definitely excluded.

Dr. G. B. BATTEN said that his own experience bore out the lecturer's opinion with regard to the considerable value of high frequency in fissures and haemorrhoids.

The members of the Section, on the proposition of Dr. TURRELL, expressed their thanks to their French confrère.

LOCAL RESULTS OF DENTAL INFECTION.

THE second Hunterian Lecture of the session was delivered before the Hunterian Society on January 11th by Mr. W. G. SPENCER, F.R.C.S., who took for his subject, "Some local results of dental infection." Mr. RUSSELL HOWARD (President of the Society), was in the chair. Mr. Spencer's lecture is printed in full at p. 131.

Sir JAMES DUNDAS-GRANT recalled some interesting cases from his own experience. One was an abscess in the parotid gland, which, on looking into the mouth, he found to be due to a feather, evidently from a pillow, which was projecting out of the orifice of the duct. Frequently he had had cases of haemoptysis brought to him, and was unable to find any cause for this condition in the chest or upper passages. He had then noticed a tooth with a polypus, and on inquiry had discovered that the patient had blood in his mouth on waking in the morning, having evidently sucked the blood from the polypus just before waking. He agreed that the incisors might be very influential in producing mischief. One reason why the pyorrhoea connected with them was so difficult to

deal with was because these were the teeth of all others most under the influence of the tongue, which kept pressing upon them and making them rock, so that the sacs around them were opening and closing with great frequency.

Dr. JOHN ANANS referred to the relative immunity of women from cancer of the tongue. He thought it a pity to remove the lower incisors, which were the most durable of all the teeth.

Mr. SPENCER, in reply to a remark by the President, said that he agreed with those dental surgeons who thought that plates should never be fixed; and yet it was wonderful what fixed plates were put in, especially in the case of persons who had been fitted in America, and how they got on without complications he did not know. With regard to the advisability of removing the incisors, it was true that often there was only a small amount of pyorrhoæa alveolaris connected with them, but they were no infective focus, and therefore it was risky to make a raw surface in their neighbourhood. Cancer of the tongue was certainly less frequent in women than in men, but it was not very rare; he thought it possible that 50 per cent. of the cases were in women.

SPASMODIC STRICTURE OF THE UTERUS.

A MEETING of the North of England Obstetrical and Gynaecological Society was held at Leeds on December 16th, the President, Mr. CARLTON OLDFIELD, in the chair. An adjourned discussion took place on Mrs. Dobbin Crawford's paper on spasmodic stricture of the uterus, read at the November meeting of the society, and printed in this week's JOURNAL at p. 135. In her original paper Mrs. Crawford related a case recently under her care, and urged the adoption of the term "spasmodic stricture" as being simpler than "hour-glass contraction" and a more accurate description of the condition. The correct treatment was deep surgical anaesthesia, and this would be found successful in all but a few obstinate cases for which Caesarean section might still be required.

Mr. MILES PHILLIPS (Sheffield) agreed that prolonged surgical anaesthesia was of the greatest value in these cases. Dr. FLETCHER SHAW (Manchester) mentioned that Clifford White had recommended prolonged traction by means of a weight attached to the presenting part. Dr. MacGREGOR YOUNG, speaking from the anaesthetist's point of view, did not think that any depth of anaesthesia would sufficiently relax the uterine muscle.

Dr. T. G. STEVENS (London), invited to take part in the discussion, strongly opposed the adoption of any new name for the condition, and thought the best treatment was deep leave such cases alone. Dr. DOBBIN CRAWFORD briefly replied.

Specimens and Cases.

Miss IVENS (Liverpool) showed a specimen of primary carcinoma of the Fallopian tube.

Dr. J. W. BRINE (Manchester) showed specimens recently removed from a case of ectopic pregnancy. The left tube contained a gestation sac which had ruptured and given rise to the symptoms demanding operation. The uterus was bicornuate, the right horn being rudimentary but enlarged at its distal end, and very like a subperitoneal fibroid in appearance. This horn was removed, and on examination was found to contain a lithopaedion. Dr. Brine also read notes of a case where two ectopic pregnancies had occurred in the same patient within a period of two years.

Dr. CROFT (Leeds) related a case of full-term ectopic pregnancy for which he had recently performed abdominal section. The breech of the child lay in the pouch of Douglas, and the placental site was over the left iliac vessels and navel. The child, which weighed 4½ lb., was delivered alive, and lived a week. The placenta was not removed, but the amniotic sac stitched to the abdominal wound and a tube inserted into it. The patient was still in hospital, but the wound was now almost healed. No pyrexia followed the operation.

OBSTETRICS AND GYNAECOLOGY.

A MEETING of the Midland Obstetrical and Gynaecological Society was held at the Medical Institute, Birmingham, on January 3rd, with the President, Professor EWEN MACLEAN, in the chair.

Mr. FURNESS JORDAN showed a specimen of myxosarcoma of the Fallopian tube. The specimen, which showed a growth

in the left cornu of the uterus and in the left tube, was from a multipara, aged 47, giving a history of twelve months' menorrhagia. At the operation numerous secondary deposits in the pelvis were found, and hysterectomy was performed solely for the arrest of haemorrhage. In connexion with this case Mr. Jordan reported the case of a schoolgirl, aged 16, in whom the sudden onset of profuse haemorrhage was accompanied by the appearance of a tumour at the vulva. The tumour was removed by the practitioner in attendance by ligation of its pedicle. Six weeks later haemorrhage recurred, and the vagina was found to be again filled with soft friable growth. This was found to be a sarcoma botryoides, and total hysterectomy was performed.

Mr. Jordan also showed a specimen of parovarian cyst complicating pregnancy. The patient, a primigravida eight months pregnant, was found to have a large cyst in the pouch of Douglas. Caesarean section at term was advised and performed, when the tumour was found to be a pedunculated parovarian cyst. Removal of the cyst at the time of its discovery was contraindicated by the undesirability of exposing the woman to labour with a newly healed scar, and tapping of the cyst at the onset of labour contraindicated by the marked preponderance of dermoids amongst cysts of this class. Mr. Jordan also reported the case of a woman, four months pregnant, with similar symptoms to the last in whom a solid tumour was felt in the pouch. The tumour, which was a fibromyoma growing in the posterior wall of the uterus, was removed by myomectomy, and the pregnancy continued uneventfully.

Dr. H. SHUFFLEBOTHAM showed a large teratoma of the ovary removed from a woman aged 34. The tumour presented as a nodular mass, filling the pelvis, and extending upwards to the umbilicus. On opening the abdomen the mass was found fixed to the back of the uterus, and many intestinal and omental adhesions were present. The tumour, which was solid, contained isolated cysts and some bone. Histologically, elements of all the layers of the trilaminar blastoderm were represented. There was no evidence of malignancy. Dr. Shufflebotham also showed a large pedunculated fibromyoma removed from a patient, aged 50, who gave a history of pain and constipation of three weeks' duration. A central tumour, extending to just above the umbilicus, was present. At laparotomy the tumour was found to be a large fibroid originating from the right cornu of the uterus, and having three complete twists in the pedicle.

Dr. W. A. PORTS read a short paper on psychotherapy in relation to obstetrics and gynaecology. Having generally reviewed the respective places of hypnosis, suggestion, and analysis in psychotherapy, he went on to show how and when these might be used in the treatment of certain obstetrical and gynaecological disorders. In particular, he thought psychotherapy of use in the treatment of labour, and of menstrual disorders associated with pain, by removing or lessening the unreasonable dread of the unknown, experienced in greater or less degree by most women.

THE West Kent Medico-Chirurgical Society held a clinical evening at the Miller Hospital, Greenwich, on January 12th, when Mr. WILLMOTT IVANS showed a case of multiple exostoses in a dwarf man; the condition was familial, his father, brother, half-sister, and sister's children suffering similarly. Mr. C. A. JOLI showed a young woman from whom he had removed the right clavicle containing a hard nodule which showed egg-shell cracking. He also showed a man, aged 43, with Pott's disease of the spine, treated with a bone graft from the tibia. Dr. HAROLD PRITCHARD showed a child which developed hard nodes on one fibula and one tibia after acute septic meningitis. He also described the treatment of a case of pernicious anaemia treated by intramuscular injections of colloidal manganese. Dr. BOWEN WILLIAMS showed a man operated on by Mr. H. Davis for stricture of stomach due to swallowing sulphuric acid. Dr. JAMESON showed a case of ulcer of the tongue with acid dyspepsia; a case was also shown of head injury, who developed spastic paralysis of the legs six years later, which was relieved by a decompression operation.

THE Ambassador of the United States to France has presented Professor Bergonié with the medal and diploma of the Franklin Institute of Philadelphia in recognition of his services to science, and more particularly for his apparatus employing electricity in the search for, and extraction of, fragments of projectiles.

Rebuelus:

THE ANATOMY OF THE ORBIT.

In his monograph *The Anatomy of the Human Orbit and Accessory Organs of Vision*¹ Professor S. E. WHITNALL of McGill University has provided the ophthalmologist and rhinologist with a most extensive and elaborate account of the details of structure and development of that part of the body of chief interest to them. The book represents in an amplified form the substance of a series of lectures delivered to candidates for the Oxford diploma in ophthalmology. The work is so complete in every other respect that it seems almost a pity that the author has not included an account of the gross and minute structure and development of the globe, but other parts are so fully described, together with the results of several original investigations, that the work becomes of real value and interest to the anatomist.

The text is divided into four parts. Part I is devoted to osteology, and includes a very clear account of the air sinuses and an important section on the growth and variation in shape of the orbit. Part II deals in minute detail with the eyebrows, eyelids, conjunctiva, and lacrymal apparatus. Part III is concerned chiefly with a description of the ocular muscles, including a simple yet efficient account of their actions, and with the blood vessels and nerves of the orbit. Part IV consists of a brief sketch of the cerebral connexions of the nerves, and it would appear that this section might be amplified with advantage to the clinician.

A perusal of the monograph is both refreshing and interesting, since it is obviously written with the primary intention of emphasizing all points which may be of real practical service in diagnosis or surgical treatment, yet the more scientific aspect has not been neglected and attention is drawn repeatedly to the limitation of our knowledge on certain points and imagination stimulated by the original manner in which some subjects are presented. Almost all parts are dealt with in an exhaustive manner, but we would mention especially the sections on the fascia of the orbit and the lacrymal apparatus. Professor Whitnall is to be heartily congratulated on the extraordinary amount of detail he has found it possible to introduce without destroying the clearness of presentation and without inducing weariness in the reader.

The text is clearly and freely illustrated, and the majority of the figures are taken from original dissections. An important and useful addition to the monograph consists of a fairly complete list of papers and books, published since 1900, relating to the anatomy, histology, and embryology of the subject. We fear the price may preclude some from purchasing a book which fulfils a long-felt want.

RENAL EFFICIENCY TESTS.

PROFESSOR HUGH MACLEAN's extensive work during the war, mainly published under the aegis of the Medical Research Council, is well known, and he has now placed the medical profession under an obligation by his clear and skilful presentation of a difficult subject in *Modern Methods in the Diagnosis and Treatment of Renal Disease*.² This book, though small in size, contains a great deal of information, more, indeed, than the title alone would lead the reader to suppose, for it deals to some extent with the clinical manifestations of acute and chronic nephritis, and includes some interesting information about war nephritis—a subject on which the author speaks with the highest authority. It is intended for the general practitioner, and accordingly only those tests which are of proved clinical value and can be carried out easily are described. In the simple scheme which Professor Maclean constructed for the examination of renal patients there is only one of the five tests—namely, that for the diastatic activity of the urine—which demands any special apparatus, and this appliance is not

complicated—only an incubator or a hot-water bath maintained at a constant temperature of 37° C.

While the great value of the chemical tests of renal efficiency is insisted on, and is emphatically shown in connexion with genito-urinary cases in which an operation under a general anaesthetic may be involved, the importance of careful clinical examination is wisely pointed out. In the critical account of the chief renal functions the excretion of acid products and the subject of acidosis in renal disease are described, the difference between renal and diabetic acidosis being clearly demonstrated. In acute nephritis oedema, hydraemia, and raised arterial blood pressure usually run a parallel course, and as a rule their disappearance is preceded and accompanied by diuresis due to the accumulation of urea in the blood and the returning functional power of the recovering kidneys. Retinal changes in acute nephritis are, Professor Maclean finds, commoner than is generally thought, may clear up, and are without the serious prognostic significance that they have in chronic renal disease.

On the basis of chemical tests cases of chronic nephritis fall into two main groups: The commonest type is the azotæmic, usually spoken of as chronic interstitial nephritis, characterized by retention of nitrogenous products and without any impairment in the excretion of water and common salt; the other, the hydraemic form, generally known as chronic parenchymatous nephritis, is characterized by difficulty in excreting sodium chloride and water and by oedema, but there is no retention of nitrogenous products. Not infrequently, however, the same patient presents the symptoms of both azotæmic and hydraemic disease.

The most important chemical test is the estimation of the non-protein nitrogen—urea, uric acid, creatinin and prerin bodies—in the blood, and for this purpose the examination for the amount of urea, a comparatively simple process, is sufficient. This test has great prognostic value; thus, if the blood contains 100 mg. per 100 c.cm., surgical procedures requiring a general anaesthetic—for example, prostatectomy—almost always prove fatal. But a fall in the high blood urea in severe renal disease, such as can be effected by diet, is not necessarily followed by improvement. For cases in which the kidneys are damaged, but not so severely as to lead to an accumulation of urea in the blood, two simple urinary tests are recommended: the author's "urea concentration" test after ingestion of 15 grams of urea, and the diastatic test, a high diastatic value in the urine pointing to renal efficiency. In addition Ambard's coefficient of urea excretion, the phenol-sulphonaphthalein and other tests are described. The chapter on the relation of nephritis to blood pressure and cardio-vascular changes clearly shows the value of chemical tests in confirming or correcting an otherwise obvious diagnosis of uræmia.

The last chapter, entitled "Some observations on the dietetic treatment of nephritis," recalls the dictum ascribed to a former authority on the subject, to the effect that "the great danger of chronic renal disease is that someone will find it out and treat it," by which was meant the virtual starvation of a milk diet. Professor Maclean carefully points out the limits of protein restriction and insists that the amount of protein prescribed should not be dictated by the degree of albuminuria. In the section on chronic parenchymatous nephritis Epstein's explanation of the beneficial effect of his high protein diet is critically discussed and the diuretic value of urea is shown by examples.

In conclusion, this well-written work, which breathes a spirit of personal investigation and experience, should be in the hands of every medical man who has not already travelled over the voluminous literature of recent years dealing with the modern conceptions of nephritis.

MENTAL DISORDER AND LEGAL RESPONSIBILITY.

*Insanity and Mental Deficiency in Relation to Legal Responsibility*³ is a contribution of definite value to psychiatry in its legal aspect, and its author, Dr. WILLIAM G. H. COOK, has rendered a distinct service to the alienist by his concise presentation of an obscure and difficult subject. His research was accepted as a thesis for the degree of Doctor of Laws in the University of London, and its purpose is to summarize and clarify the legal principles relating to the civil responsibility of the insane.

³ *Insanity and Mental Deficiency in Relation to Legal Responsibility: A Study in Psychological Jurisprudence.* By William G. H. Cook, LL.D. London: George Routledge and Sons, Ltd. New York: E. P. Dutton and Co. 1921. (Demy 8vo, pp. 192, 10s. 6d. net.)

¹ *The Anatomy of the Human Orbit and Accessory Organs of Vision.* By Professor S. E. Whitnall, M.A., M.D., B.Ch.Oxon., M.R.C.S., and L.R.C.P.Lond. Oxford Medical Publications. London: Henry Frowde, 35a, net.) 1921. (Demy 8vo, pp. 413, 195 figures.)

² *Modern Methods in the Diagnosis and Treatment of Renal Disease.* By Hugh Maclean, M.D., D.Sc., Professor of Medicine, University of London, and Director of the Medical Clinic, St. Thomas's Hospital. London: Constable and Co. 1921. (Demy 8vo, pp. viii + 162, 4 figures, 5s. 6d.)

As the author points out, while the law relating to the criminal responsibility of lunatics has reached a comparatively advanced stage and definite rules have been laid down for courts when dealing with cases in which the person convicted of crime pleads insanity, no such precision exists in regard to civil responsibility. Altogether the law relating to the civil responsibility of lunatics is in an indefinite and unsatisfactory state, and the present volume is the only modern work in which the subject is adequately treated. In successive chapters Dr. Cook deals with mental deficiency—a term here used in its widest sense—in relation to tort, the law of contract, marriage, divorce, and testamentary capacity. The law in respect to these subjects is dealt with historically, and legal decisions in over two hundred important cases are referred to in the text. A full discussion of the law in various countries is included in the various chapters, and the summary given of the laws of ninety-one other countries relating to insanity as a ground for divorce is perhaps of particular value and interest in view of the attempts which are being made to change the English divorce law at the present time. The author's survey makes it clear that the laws of several non-Catholic foreign countries, as well as those of New Zealand and of Western Australia, evince a tendency to regard the contract of marriage as voidable upon proof of the confirmed insanity of one of the parties. One of the most valuable chapters in the book from a purely practical point of view is that concerned with testamentary capacity and insanity. It is in relation to this question that the physician is most likely to be involved in his practice as far as the civil responsibility of a lunatic is concerned, and most practitioners would be well advised to master Dr. Cook's clear and able survey of the attitude of the law towards wills made by those who are subsequently alleged to have been insane.

In concluding this volume Dr. Cook makes some suggestions for the reform of administration relating to lunacy and mental deficiency. His view is that the Board of Control should be made a sub-department of the Ministry of Health, and that it should become the central authority for the care and treatment of all persons of unsound mind. He advocates, moreover, the abolition of the Statutory Committee of county or county borough council set up by the Lunacy Act, 1890, and the transference of all its powers and duties to the central authority. It is difficult to see how the proposed changes would be to the advantage of the institutions concerned. The Central Lunacy Board should certainly retain its control over the medical treatment, discharge and detention of patients, but it is another matter where administration is concerned. The visiting committees are in a position to carry out the business management of the asylums more efficiently and economically than is a Government department, and they constitute furthermore a useful court of appeal for patients in asylums and their relatives. No Government department could be so accessible or so sympathetic as is the elected local representative of the ratepayers.

This book can be unreservedly recommended, and the author is to be congratulated on having filled a gap in the literature of psychiatry.

PATHOLOGY AND TREATMENT OF SYPHILIS.

The first of two volumes on syphilis in the *Traité de Pathologie Médicale et de Thérapeutique Appliquée*,¹ edited by EMILE SERGENT, L. RIBADEAU-DOMAS, and L. BABONNEIX, deals with generalities and with the disease in the adult; the second with the signs and symptoms it produces in early life.

The account given of the general pathology of the disease is excellent and embodies an adequate summary of animal experiments, and of the application of the results thereby obtained to the treatment of syphilis in man. After a description of the various drugs used in the treatment of the disease and their mode of administration, we find a discussion of the situation with regard to syphilis and marriage. The authors admit that in spite of advances in our scientific knowledge of the disease, rules on the subject of marriage are still lacking in precision and scientific accuracy. A

pathological condition of the cerebro-spinal fluid must, they consider, be regarded as an absolute contraindication to marriage. On the other hand, considerable discrimination must be exercised in giving or withholding permission to marry. If too high a standard be set up there is a danger that the medical man will not be consulted.

The chapters containing the discussion of these introductory considerations are followed by others dealing with syphilis of various structures, both visceral and peripheral. Dr. Clement Simon contributes the section on syphilis of the skin, mucous surfaces, and lymphatics. The remarks on skin lesions are well illustrated by photographs. The sections on syphilis of the bones and joints, of the nasopharynx and larynx, and of the respiratory organs and mediastinum, contributed by Rostaine and Bellin and Mirande respectively, are remarkably complete, the subjects being treated in considerable detail. Rostaine contributes the chapters on syphilis of the circulatory and genito-urinary systems, and Babonneix the important section dealing with the nervous system. Altogether the contributors have been well selected, for their names are associated with the subjects on which they write. By the collaboration of these experts a mass of material has been collected between the covers of a single volume and presented in a concise and readable form. The work is in the nature of a general review of the subject of syphilis, whilst at the same time the authors have succeeded in preserving much of the force of an original memoir. It will certainly be useful as a book of reference not only for syphilologists but for specialists in various branches of medicine and surgery. If we have to give expression to any regret it is that there is no bibliography to enable the reader to refer to the original work when desired.

The question of economy has apparently been borne in mind in the production of the volume, otherwise additional illustrations might with advantage have been inserted in several of the sections. We confidently recommend it to all who desire an up-to-date reference work on this subject. We do not know of any other modern book that covers the same ground so successfully.

The second of the two volumes deals with syphilis in early life. It is divided into three parts—on acquired syphilis in infancy, by Dr. P. Fernet; on congenital syphilis in infants, by Dr. Edmond Fournier; and on late congenital syphilis, by Dr. P. Fernet. Nearly four-fifths of the volume is, naturally enough, devoted to the full consideration of ordinary congenital syphilis. After an interesting account of the ways in which syphilis can be acquired in early life, Dr. Fernet discusses the diagnosis between acquired and congenital syphilis; this rests on the absence of certain manifestations, such as erythema, palmar and plantar pemphigus, and pseudo-paralysis, and the presence of a chancre and of more obvious enlargement of the lymphatic glands in the acquired form. The same author's description of late or delayed congenital syphilis owes much to Professor A. Fournier's epoch-making work on this subject, and gives an interesting account of the various dystrophies that may occur and of their relation to the endocrine glands, to which responsibility is unhesitatingly attached. In the treatment of such cases treatment by antisyphilitic drugs should therefore be supplemented by extract of the endocrine gland thought to be affected—for example, of the thyroid in hypothyroidism, and of the testis or ovary in infantilism. Dr. Edmond Fournier's well illustrated description of ordinary congenital syphilis begins with some general remarks on congenital syphilis in the second generation, with a report of a case in the third generation, on the influence of congenital syphilis on the descendants, and on marriage and syphilis. He is fully conscious of, and thus partially disarms, the opposition which his opinion, that a person with syphilis, whether congenital or acquired, should not marry, must arouse. The early manifestations of the congenital disease are fully described, and then a detailed account of the visceral and bony changes given. In the account of the relation of congenital syphilis to rickets it is pointed out that the antagonism excited by Parrot's well-known view—that rickets is a manifestation of luetic infection—has been followed by a counter-reaction, and stress is laid on the special frequency of rickets in the subjects of congenital syphilis and on Kirmisson's arguments in favour of the connexion between these two conditions. In addition to many references to the work of others, Dr. Fournier has brought in many observations of his own, and thus provides the reader with a wide and suggestive monograph on this important subject.

¹ *Traité de Pathologie Médicale et de Thérapeutique Appliquée*. Publié sous la direction de Emile Sergent. Tome XIX: Syphilis; Génér. pp. 688; 109 figures, 1 planche. Paris: A. Maloine et Fils. 1921. (Demy 8vo. 273; 65 figures, 8 plates. Fr. 18.)

EARLY CIRCULATORY DISEASE.

Dr. R. McNair Wilson is the author of a volume entitled *The Clinical Study of the Early Symptoms and Treatment of Circulatory Disease in General Practice*,⁵ dedicated to the workers at the St. Andrews Institute for Clinical Research, and to Sir James Mackenzie, who supplies a foreword. This book is an exercise in the clinical method, and distinguishes between the effects of disease and the reactions of the body to these effects, as shown in the circulation. It contains an investigation into the mechanism of the variations of the pulse rate in health and disease, based on the analysis of a large number of personal observations. Dr. Wilson believes that the distinction between vagal activity and sympathetic activity as occurring at different times is incorrect, and that there is a continuous reciprocal reaction. Thus external stimuli of the skin and other sense organs primarily excite the vagus, and so would slow the heart, but this vagal "pull" is normally followed by a reflex response on the part of the sympathetic, and an increased pulse rate, which in many cases so dominates the picture that the preliminary vagal effect is not noticed; mechanical stimuli from within, such as food, the foetus in utero, menstruation, and pathologically a renal calculus, or a "controlling" appendix, first excite the sympathetic, but a reflex vagal response follows and often dominates the scene; if now external stimuli, mental or sensory, occur, the vagal activity is intensified, and as a result nausea, vomiting, exhaustion, and fainting are prone to follow. By their toxins the infections, other than those of the typhoid and paratyphoid group, render the vagus irritable and more susceptible to external stimuli; hence the vagus is continually making a call on the sympathetic for response, thus causing a rapid pulse: exhaustion may follow, because the reciprocal action of the sympathetic fails from depletion, and the heart and other organs do not react properly. The truth of the statement, at first sight paradoxical, that an irritable vagus may cause tachycardia is shown by the slowing of the pulse that follows a small dose (1-200 grain) of atropine. The toxins of typhoid and paratyphoid are exceptional in exciting the sympathetic and so producing a vagal response, as seen by the relatively slow pulse.

With this conception of the reciprocal action of the vagus ("the nerve of diastole") and the sympathetic ("the nerve of systole") in mind Dr. Wilson ingeniously analyses the various manifestations accompanying cardiac disorder, such as breathlessness, cyanosis, hyperalgesia, and cardiac pain, and thus provides much stimulus for thoughtful investigation by practitioners working on the lines of the St. Andrews Institute for Clinical Research; but it should be pointed out that, although the words "general practice" come into its title, this book stimulates thought rather than provides dogmatic help for the immediate successful treatment of cardiac disease in the course of busy practice.

X-RAY DIAGNOSIS.

The book on x-ray diagnosis, by Dr. HENNERT ASSMANN of Leipzig,⁶ is perhaps the most comprehensive which has hitherto appeared. Unlike many of the standard works on radiology, it contains no introductory chapter on instrumentation and technique, and throughout very few instruments are illustrated. In its main construction the work divides itself into four parts. The first is a comprehensive treatise on the heart and great vessels, with a short chapter on the mediastinum. This occupies 146 pages, the normal and the abnormal being both fully discussed and illustrated. The diagrams are a distinct feature of this part. The second deals in detail with the lungs and pleura in about the same number of pages, and is profusely illustrated by radiographs of both usual and unusual pathological conditions. The gastro-intestinal tract is discussed in 250 pages. In the concluding portion are found sections dealing with, amongst other things, the liver and gall stones, the diagnosis of kidney conditions, various abnormalities affecting the bones, and so on.

The whole is essentially German in its style, its scope, its wealth of detail, and the painstaking method which is obvious on every page. It is also essentially German as

evidenced by the fact that, with a few exceptions which go to prove the rule, the whole of the extensive bibliography which is added at the end of each section consists entirely of German and Austrian references. A perusal of the work and its references leads the reader to the inevitable conclusion that no x-ray work of any kind has ever been done outside of Germany and Austria, not even by those of German nationality or extraction who have the good fortune to live in other countries. Having, however, made this criticism—which is a fair one—one cannot fail to recognize the general merits of the book. As a work of reference for an x-ray worker who understands the German language, and who is also prepared to wade through a considerable amount of detail in order to extract essentials, it should be invaluable. Nearly 700 pages of letterpress and 633 illustrations speak for themselves. These illustrations are extraordinarily good, and cost has apparently been of no consideration. Many excellent diagrams and reproductions of both photographs and radiographs appear on almost every page, whilst in addition there are some twenty pages of reduced bromide prints which illustrate all the more important points of x-ray diagnosis. These are of great excellence and are admirably chosen. Further, both the printing and the paper are of the best. It is not too much to say that the illustrations and diagrams alone are so complete and good that the book will be of value to any radiologist even if he knows no German and so cannot read the letterpress.

THE PHYSIOLOGY OF BACTERIAL INFECTION.

PROFESSOR MAURICE ARTHUS has produced a most readable *Précis de Physiologie Microbienne*.⁷ He describes how he was led to undertake his task because all the existing books on this subject gave too large a place to technical considerations and to mere theories. Accordingly he has omitted all description of technique employed in bacteriological and serological practice. His book is not illustrated with diagrams portraying Ehrlich's side-chain theory, nor is it encumbered with the ponderous terminology such expositions necessitate. The known facts are stated with regard to each problem dealt with and the logical deductions carefully considered. The author makes no attempt to disguise his partisanship, for he is a devotee of the "cellular," as opposed to the "humoral," school of thought.

The earlier chapters of the book, which deal with the nutrition and enzyme action of bacteria, are clearly written and the subject matter attractively presented. But the description of bacterial species is somewhat meagre and not altogether free from errors, such as that which occurs on page 110, where the author states that protozoa cannot be cultivated. In subsequent editions attention should be drawn to the fact that spirochaetes, trypanosomes, and some amoebae can be cultivated with ease. The next following chapters deal with immunity problems, such as anaphylaxis and the different properties of normal and immune serum. In discussing the manner of action of complement or alexine, the author points out that, strictly speaking, this substance is neither "fixed" nor "deviated," and therefore to describe the disappearance of complement in immunity reactions, he employs the phrase, "consummation de l'alexine." This will illustrate with what assiduity the writer attempts to escape from the compromising effect of inaccurate terminology. He makes his meaning clear in all he has to say about immunity. For him phagocytosis is the basis of the protective properties of both normal and immune serum, and the leucocyte is the pivot on which immunity rests.

This book will appeal to all interested in the theoretical aspects of resistance to infectious disease, but owing to the complete absence of a bibliography and references it is unlikely to replace the existing standard textbooks on immunity.

NOTES ON BOOKS.

MADAME BÉROT-BERGER'S little book on the science of infancy⁸ is the last of a series of five from her pen on subjects of medico-social importance. With the French the dwindling birth rate has long been a matter of grave concern, and the authoress has taken a worthy and practical part in conserving the vital resources of the nation. In 1913 the Strauss Act was passed. It has been described as the Baby's Charter.

⁵ *The Clinical Study of the Early Symptoms and Treatment of Circulatory Disease in General Practice*. By R. McNair Wilson, M.B., Ch.B. With a Foreword by Sir James Mackenzie, M.D., F.R.S., F.R.C.P. Oxford Medical Publications. London: Henry Frowde, and Hodder and Stoughton, 1921. (Demy 8vo, pp. 245, figures 111, 15s.)

⁶ *Die Röntgendiagnostik der inneren Erkrankungen*. By Dr. Herbert Assmann. Leipzig: F. C. W. Vogel, 1921. (Imp. 8vo, pp. 693, 15s.)

⁷ *Précis de Physiologie Microbienne*. Par M. Arthus. Paris: Masson et Cie, 1921. (Cr. 8vo, pp. 403. Fr. 17 carbonné; Fr. 19 net.)

⁸ *L'Enfance, pour le développement général des Tout-Petits*. Bérot-Berger, Membre du Conseil Supérieur de la Natalité, oïne et Fils. 1921. (Cr. 8vo, pp. 90. Fr. 5.)

because under it a fixed daily sum was paid to every working woman in the last four weeks of pregnancy, and for four weeks after her confinement; it authorized also a small financial dote to the working woman who, often at financial sacrifice, nursed her infant for the first year of life. For years before this Madame Bérat-Berger was at work in the industrial towns of Northern France, where the exigencies of female labour in the factories levied a heavy toll of infant life; in certain towns in the Department of the Aisne the organizations she created effected a great reduction in the infant's death rate. Her contribution to the problem was twofold: first, by making it possible for factory women to suckle their infants and continue at work; secondly, by the formation of nurseries for little children from one to four years of age where during the day they were fed and their education in every sense, physical and moral, was carefully supervised by trained workers. The account she gives of this work is enthusiastic; it is supported by minute clear details as to the equipment, personnel, and management of these "garderies d'enfants." The book is written for the guidance of voluntary workers in France in the cause of child welfare, but it can also be recommended to the notice of those engaged in similar work in this country. It cannot fail to be of interest, and may very well also convey valuable practical suggestions for the organized efforts now being widely made on this side of the Channel towards the same end.

THE ninth volume of *Collected Studies*⁹ from the Bureau of Laboratories of the City of New York contains some sixty original papers written during the years 1916-1919 on a great variety of what may broadly be termed public health questions. Many of them deal with the prophylaxis or treatment of meningitis and poliomyelitis, others with bacteriological detail of all sorts, others with the practical problems of sanitation—such as the bacteriology of public swimming baths. The book should be accessible to all medical officers of health and public health laboratories.

The *Pharmacopœia of the University College Hospital*¹⁰ is a neat little waistcoat-pocket volume, and, in addition to the formulæ commonly forming the bulk of such books, contains over twenty special tables, lists, and directions of service to medical students and practitioners. It is interleaved for the user's convenience.

⁹ *Collected Studies from the Bureau of Laboratories (Foot of East 16th Street) City of New York.* Dr. W. H. Park, Director. Vol. ix, 1916-1919. City of New York, Department of Health. (Sup. roy. 8vo, pp. 491; 12 figures.)

¹⁰ *Pharmacopœia of the University College Hospital.* Edited by C. H. Hampshire, B.Sc., Lond., F.I.C. London: J. Bale, Sons, and Danielsson, Ltd. 1921. (3 x 6, pp. 55. 4s. net.)

MEDICAL AND SURGICAL APPLIANCES.

Intratracheal Medication.

IN view of the present epidemic of influenza, with frequent involvement of the larynx, trachea, and bronchi, Dr. A. R. FAÏEL thinks that medical men may be interested to be referred to the method recently devised by Professor Leduc of Nantes for the introduction of medicated oily fluids into the trachea by the patient himself, as illustrated in the diagram. It is simple and efficacious. Half a

teaspoonful of oil of almonds containing 1 per cent. of menthol or 1 per cent. of phenol, or both combined, is poured into the wide curve of the glass tube; the short curve is placed far back in the pharynx, the lips tightly closed round the stem, and an inspiration made through the tube. This carries the fluid into the trachea. Each dose can be repeated twice or thrice at a time, and the treatment carried out four or five times daily. No coughing is caused. The tubes can be obtained from Messrs. Mayer and Phelps, New Cavendish Street, W.1.

Snook Apparatus.

Messrs. NEWTON AND WRIGHT, Hornsey Road, London, describe in their latest catalogue some new types of the Snook apparatus which was first manufactured by them in 1903. Amongst other patterns, perhaps the most interesting is that described under the title of "the universal model." This machine is stated to be capable of passing 150 milliamperes through a Coolidge tube at a 5-inch spark gap, and to be suitable for deep therapy with a tube working at an alternation gap of 12 inches. The machine is oil-insulated.

LUNACY ADMINISTRATION.

CONFERENCE OF MEDICAL SUPERINTENDENTS AND CHAIRMEN OF VISITING COMMITTEES.

A CONFERENCE on lunacy administration was held in London on January 19th and 20th, at the instance of the Board of Control, and was attended by the medical superintendents and chairmen of visiting committees of practically all the mental hospitals of England and Wales. Sir FREDERICK J. WILLIS, Chairman of the Board of Control, presided, and was accompanied by the Commissioners. The proceedings appeared somewhat inconclusive, owing to the chairman's refusal to take resolutions, although on certain matters there was an avowed division of opinion, but it was understood that the Board would be guided by the measure of general assent given to the views expressed, apart from an actual vote. On one matter only the chairman asked for a decision of the Conference. This was the proposal that means should be provided for early treatment without certification, and it commanded the unanimous assent of the Conference. On a further point, that the Board of Control should be the supervising authority with regard to early treatment, there appeared to be only one dissident.

Sir ALFRED MOND, the Minister of Health, in welcoming the members of the Conference, said that mental disease was only one aspect of disease generally, and in the proportion in which it lost its stigma early treatment would become practicable. If alteration of the law was necessary to secure this end, it would have to be the result of very general agreement on the part of those best able to speak on the subject. The Minister of Health went on to speak of the duties of a medical superintendent, saying that the best use was not made of his attainments if he was compelled to spend very much of his time in routine work. He hoped some means might be found for relieving him from such pressure, and also for providing assistant medical officers with opportunities for post-graduate study.

Early Treatment Without Certification.

The first subject discussed was early treatment (in-patient and out-patient) at mental or general hospitals without certification. Dr. EDWIN GOODALL (Cardiff) supported the policy of the Mental Hospitals Association, that certain institutions should be taken over as psychiatric clinics, and that these should have no association with lunacy or lunacy law. He deplored the complete segregation of all mental cases, and believed that mental disease should be brought into the broad sanctuaries of general medicine. His plan was a system of primary, secondary, and tertiary centres, on the lines of the Dawson report. At the primary centres, in the remote parts, the patient would be attended by the general practitioner, and hydrotherapeutic and other forms of treatment would be available. At the secondary centre, in a larger town, there would be special wards as well as an out-patient department, with some medical men with special experience in these diseases. At the tertiary centre there would be a separate building for the reception of these cases, and the help of specialists would be available. This tertiary centre would be in a town where there was already a general hospital and medical school. A research institute should also be set up. He was anxious that the whole of this arrangement should be dissociated from mental hospitals. The idea of making it a part of mental hospital organization was one of the compromises dear to the Anglo-Saxon mind.

Professor SHAW BOLTON (Wakefield) took a different view. If this was a new country, with no previous experience of lunacy administration, he would favour the reform suggested by Dr. Goodall, but as it was, he believed it more practicable to work within and to improve the present system. He did not like the prospect of all early cases being removed from asylums, which in that event would be mere gaoles. His plan was the provision of an out-patient department and the use of a well-equipped hospital of moderate size, attached to the mental hospital, but involving no question of legal detention or certification. There was an out-patient department attached to his own institution, and those who attended came largely on the recommendation of other patients. He wanted official permission to classify patients; at present if the medical officer permitted any considerable latitude as between one patient and another, he was personally responsible in case of accident.

Dr. T. S. GOOD (Oxford) urged the provision of early clinics, which should be called nervous disorders' clinics, not mental clinics, attached to general hospitals, on the ground that

general hospitals were more accessible than mental hospitals, and more comprehensively equipped, and that it would be possible for the general hospital staff to work with the psychiatrists as a united team. Alderman J. G. TAGGART (Chairman, Mental Hospitals Association) regretted that the Board of Control had not given a lead on this matter. His association was unanimously in favour of the introduction of legislation by the Government enabling clinics to be set up for early treatment. He wanted mental experts to be available outside the asylum walls. Lunacy was the only disease of which it might be inferred from the attitude of the authorities towards it that prevention was not better than cure. He did not want the Board of Control to be associated with these prospective centres. Sir GEORGE TRUSCOTT (City of London) said that although his committee's mental hospital was seventeen miles from the city, he thought there would be no difficulty in setting up out-patient departments, one at the hospital itself, and another in the city, at the offices, where one of the medical staff could attend. He wanted any legislation to be permissive, and to be embodied in a short bill, not in an omnibus measure like that proposed in 1920. Sir W. HODGSON pressed for legislation to give enabling powers to local authorities to carry out early treatment, whether by clinics or otherwise.

Dr. HUNTER BORN, speaking as a Commissioner of the Board of Control, deprecated too much insistence on legislation, and pointed out the difficulties with regard to those patients who did not and could not come voluntarily for treatment. Here would be the rock in the passage of legislation. If it was proposed to legislate that such persons should be taken into clinics or mental hospitals without being certified, a section of the public would say that the safeguards of the lunacy laws were being relaxed.

Dr. BEDFORD PIERCE gave an account of an experiment at York where, for the last two years, borderline cases had been received at two comfortable country houses which had been adapted for the purpose. Of the 66 patients received, 13 had recovered, and of those who failed to recover, 13 had subsequently to be certified. The houses were conducted on a voluntary basis, and if a patient became so disordered as to require certification he had to be removed. The individualized medical and nursing care required was considerable, and he did not think that such homes could be conducted at less than six or seven guineas a week for each patient. Dr. WOLSELEY-LEWIS (Maidstone) suggested as a start that the existing mental hospitals should rent one or two houses geographically separate from the institution, but administratively connected, so that the treatment of all mental disease would be in the hands of one and the same authority.

The view that the Board of Control should have charge of the arrangements for early treatment found general acceptance. Dr. RUTHERFORD JEFFREY (Bootham Park) thought that cases for early treatment should be compulsorily notified to the Board. It was not easy to see how there could be control for one group of cases and no control for another. All mental illness affected conduct, and those who treated the early cases deserved protection. Dr. W. F. MENZIES (Cheddleton) and others also thought that the necessary powers should be vested in the Board of Control. One of the Commissioners on the legal side, Mr. A. H. TREVOR, said that the legal members of the Board had always been in favour of the alteration of the law in the direction now suggested. They were anxious to see the law relaxed to permit of early treatment of incipient cases. These early cases should be medically treated without certification for a period, subject to necessary safeguards, and should be kept separate from lunacy cases, though it would be necessary to inspect the treatment afforded. He thought it would be inadvisable to have two Government departments concerned in all this administration, and the Board of Control seemed to be the only authority to carry out this reform.

The CHAIRMAN asked whether he might convey to the Minister of Health the unanimous feeling of the Conference that proper arrangements should be made for the early treatment of mental cases without certification, and that it must be ensured that the places where such early treatment was provided were properly equipped and conducted.

To this proposition the Conference signified unanimous agreement, and to the further point, that the Board of Control was the proper authority to undertake the necessary supervision, there was only one objection, from Alderman TAGGART, who, while willing that the Board of Control should give its approval to the building and equipment, desired that it should not interfere with the management.

Research and Pathological Work.

The organization of research and pathological work was very briefly discussed. Sir FREDERICK MOTT gave an account of the work at Maudsley Hospital, and pleaded for more encouragement to medical men to enter for the Diploma in Psychological Medicine. The kind of research which he desired to see carried out would involve the adequate staffing of mental hospitals with young, energetic medical officers having the right spirit of investigation. Dr. T. P. COWEN (Rainhill) said that too often the pathologist had been regarded as a junior assistant medical officer and had to work isolated and at a disadvantage. He mentioned that the laboratory at Rainhill had been affiliated with Liverpool University, and the benefit had been mutual. Dr. B. H. SHAW (Stafford) emphasized the importance of having the laboratory staff working in close association with the clinical officers. He thought that certain mental hospitals, suitably situated, might have a laboratory and staff capable of undertaking the tests necessary for complete diagnosis, and relieve the necessity for expensive local laboratories; such an arrangement might form the nucleus of an organized laboratory system throughout the country.

Medical Staff and Superintendent's Duties.

The delegation of the duties of medical superintendent was next discussed. Dr. M. A. ARCHDALE (Cambridge) said that in the multiplicity of his administrative duties the medical superintendent tended to become a sort of combination of prison governor and hotel manager, and to get rusty in his medical knowledge. A way must be found whereby the medical superintendent could keep control over his institution and yet not exhaust himself in the details of management. He suggested that in the smaller mental hospitals the medical superintendent should have a non-medical private secretary to relieve him of a good deal of his administrative work, and that in the larger it should be a rule for the second physician to carry on the administration of the hospital under the general direction of his chief, the first officer to be called the medical director and the second the medical secretary. Dr. C. F. BARNHAM (Claybury) thought that a new post of sub-administrator, akin to that of registrar of a military hospital, might be created, and only matters of great importance or new policy would then be referred to the medical superintendent.

The DEAN OF LINCOLN said that what the medical superintendent wanted was a bursar secretary, who should be appointed, supervised, and, when necessary, discharged by him. Sir MARRIOTT COOKE (a Commissioner) thought that the medical superintendent might do all the work that was essential in the way of administration and still be able to encourage his medical officers in the pursuance of new systems of treatment, and so forth. Another Commissioner (Dr. H. J. BOND) said that he could not understand what the pothor was about: the medical superintendent could do as much or as little in medicine as he liked, and he had only to tell his committee if he had not the necessary officers to whom to delegate his duties.

Study Leave and the Diploma.

In opening a discussion on study leave, Colonel J. R. LORD (Horton) said that the special committee of the Medico-Psychological Association which had been appointed to consider this and cognate questions would, he believed, recommend that county councils should require that all medical officers should obtain the diploma in psychological medicine before their posts were confirmed, or at least that they should go through Part I of the course. Sir WILLIAM HODGSON objected to this requirement being urged at the present moment. It was not true to say that no special training had been afforded hitherto in mental diseases, and it was not wise to place too many impediments in the way of committees in making their selection. Dr. W. F. MENZIES said that committees got what they paid for, and generally more. Years ago the salaries of assistant medical officers were certainly insufficient, and in many cases this was still true. He did not make that complaint of his own institution (Staffordshire Mental Hospital), where the salary of the assistant medical officer started at £700 and rose to £850, with an additional £50 for the diploma.

Dr. E. GOODALL pointed out the educational argument for psychiatric clinics. At present there were only about three places in Great Britain where instruction in psychiatry could be obtained—in the new hospital attached to Bethlem, at the Maudsley Hospital, and at Dr. Robertson's clinic in

Edinburgh. It was a fallacy to suppose that instruction could be obtained by perambulating the asylums. What was wanted was something on the scale of American and Continental clinics, like those at Baltimore, and Chicago, and Munich. Dr. HUBERT BOND associated himself with Dr. Goodall, and suggested that advertisements for medical officers should indicate a preference for holders of the diploma, or should even state that, if an officer without the diploma were appointed facilities would be given for study leave. Dr. D. G. THOMSON pointed to the example of the army and public health services in granting study leave, and said that the root of the difficulty in mental hospitals was under-staffing. Dr. R. H. COLL was inclined to regard the diploma for the time being as a highly specialized attainment, and one which ought not to be required unless it was clearly the intention of the candidate to remain permanently in medico-psychological work.

Women Assistant Medical Officers.

The question of the more frequent appointment of women assistant medical officers was raised by Dr. J. E. P. SHERA (Bath), who praised the capabilities of women, while pointing out certain administrative embarrassments. Dr. W. D. MOORE (Holloway Sanatorium) agreed that women officers were capable, well informed, and painstaking, though occasionally hasty in judgement and lacking in the sense of proportion. He doubted whether medical women considered mental hospital work a career. His own institution had had ten medical women as junior assistant medical officers during the last thirty years; seven of these had left to engage in other forms of work, apart altogether from mental hospitals, and two had resigned owing to ill health. Dr. BEDFORD PIERCE and others paid tributes to the value of the woman officer.

Visiting Specialists.

The advantages afforded to the staff, both in the way of practical help and moral stimulus, by visiting specialists, were instanced by Dr. R. WORTH (Wandsworth), and several medical superintendents gave particulars of the services given by specialists and the fees paid to them.

Classification of Patients.

Dr. R. C. TURNBULL (Severalls) introduced a discussion on this subject. He thought it a mistake to classify patients entirely according to their mental state. Classification was of chief importance with regard to recent cases. Each hospital should have small additional villas for recent cases which were restless and excited; also convalescent villas at a distance from the main hospital. Dr. DAVID RICE (Norwich) thought it desirable to concentrate on keeping one ward at as high a level as possible for recoverable cases. Intellectual and social considerations were important, and he would put a mild epileptic into a ward with recently admitted and recoverable cases if this seemed justifiable on the ground of behaviour and intelligence. The minimum classification for small hospitals was (1) recovering, (2) recoverable and "asylum sane," (3) epileptics and middle-grade chronic, (4) turbulent and lower-grade chronic, (5) infirm, (6) dysenteric and tuberculous. Dr. J. R. LORR said that at Horton the classification was into recoverable and non-recoverable types; it did not matter what the type of insanity was, if there was a chance of recovery the patient should be kept in the recoverable category. Dr. S. J. COLE did not agree with this segregation into recoverable and non-recoverable, and quoted the experience of the Psychiatric Research Institute in Germany to show that dissociation between clinics and asylums had been carried too far.

Dietary of Patients.

The subject of dietary was introduced by Dr. T. C. GRATES (Birmingham), who pleaded for variety and for regard to the individual patient, especially his customary habit, active or sedentary. Dr. R. W. BRANTHWAITE, one of the Commissioners, said that, on his visits of inspection, in nearly all institutions he found the dietaries insufficient in fat-soluble A and water-soluble B. The food was reasonably varied, but more general use should be made of green vegetables and of flour which was not denuded of the grain embryo. Dr. W. F. MENZIES begged the Board of Control to represent to the Ministry of Health the undesirability of too much economy by local authorities in the provisioning of mental hospitals.

General Administration.

The Conference left much of its agenda unfinished owing to lack of time, and a scheme brought forward by Dr. J. R.

LORD for effecting general improvements in lunacy administration was not discussed. His proposal, as briefly outlined to the Conference, was that the country should be divided into a few convenient areas, and that for each area there should be created by the Ministry of Health an advisory committee on mental hygiene composed of lay and medical members elected by each authority having charge of the insane. This body would advise the Board of Control and the local authorities on such matters as the prophylaxis of insanity, after-care of discharged patients, the provision of clinics, the training of staffs, the establishment of laboratories, and general administration of mental hospitals.

A communication from Dr. J. MIDDLEMASS (Sunderland) was read, pleading for the extension of the voluntary boarder system in county and borough hospitals, and arguing that this would facilitate early treatment, and also proper treatment, of cases in which there were recurring attacks with sane intervals.

The question of the nursing staff was not discussed at any length because certain negotiations are now proceeding. On another matter, the CHAIRMAN said that the Board had appointed a small committee to consider the revision of case-books and other records. In declaring the Conference at an end, he expressed a hope that such a conference might be a periodical, perhaps an annual, event.

THE WORK OF THE MEDICAL RESEARCH COUNCIL, 1920-21.

(Concluded from page 111.)

Problems of Child Life.

AN important part of the expenditure of the Council is devoted to an extensive scheme for the study at many centres of problems of child life; the practical object immediately in view is to secure knowledge, at present greatly lacking, which may be a sound guide to the conservation of healthy life in the child before and after birth. The account given in the report of these investigations is appropriately divided into two sections—pre-natal and post-natal studies. The minds required for the one section are not necessarily apt for the second; indeed, speaking generally, the obstetric pathologist excels in the ante-natal and the pediatric pathologist in the post-natal work. It is largely the result of the stimulus given to investigation by the Medical Research Council that we find such skilled obstetric and pediatric pathologists available to carry out these studies at the present time.

The report on the pre-natal studies is somewhat disappointingly promissory in character. Statements that certain pieces of work are ready for publication, are almost ready, have been reported on preliminarily, or are being carried forward, are not so attractive as definite information would be. An exception to this general character is found in the work from the Edinburgh Royal Maternity Hospital, where Dr. F. J. BROWNE has published two important articles, the one on the causes, pathology, and prevention of stillbirths, with full histological details, and the other on syphilis of the newly born; of the former a fairly full summary appeared in this JOURNAL, and the latter was published in the *Journal of Obstetrics and Gynaecology of the British Empire* in its summer number. From these published papers two conclusions can be drawn: the first is that syphilis is a remarkably frequent cause, not only of stillbirth, but also of early post-natal death; and the second that an extraordinary number of stillbirths fall within the hopeful purview of prevention by adequate ante-natal supervision. The researches on stillbirths by workers in Glasgow, London, Liverpool, Leeds, and Cardiff are all in a forward condition; and the Medical Research Council, anticipating difficulties in co-ordinating the results from these various centres, have appointed a small committee, consisting of Professor Noel Paton, Dr. Ballantyne, and Dr. Eardley Holland, to consider the arrangement of the records. Other subjects falling within the group of pre-natal studies are those dealing with problems of pregnancy and lactation; here again some very promising reports seem to be in preparation, and Drs. James Young and Douglas Miller of Edinburgh published last April in this JOURNAL an article on the etiology of eclampsia, in which great causal importance is ascribed to placental infarcts. Dr. J. A. Stephen of Aberdeen is at work on the pathological lesions underlying the commonly reported

deaths from "prematurity"; and by and by we shall have some light on the effect of social and industrial conditions during pregnancy, from the analysis of the data obtained at the various ante-natal clinics which are carefully filling in schedules.

The post-natal studies are in a more forward condition as regards publication than the pre-natal ones. Miss Gladys Hartwell has published the results of feeding lactating rats on excessive amounts of different proteins; the effect on the litter was bad. Five articles on metabolism in infants have been published by Dr. G. B. Fleming of Glasgow and Dr. J. A. Gardner of London dealing with the respiratory exchanges and with sterol metabolism respectively; and work on acidosis in atrophic infants done by Dr. Ruth Gny (of Johns Hopkins University) at the Royal Hospital for Sick Children, Glasgow, has also appeared. A most important conjoint investigation is in progress in connexion with the influence of various factors on nutrition and growth. It is being founded on the study of the schedules used at the Welfare Centres in Glasgow, Edinburgh, Dundee, and Rosyth; the medical officers of health of these towns have been appointed, along with Dr. Stephen of Aberdeen and Dr. Leonard Findlay, a subcommittee to direct and advise on the investigation of post-natal problems. Some of the results of the study of nutrition and economic conditions in Glasgow and Vienna have been published by Miss A. M. T. Tully, Miss Madge R. Gribbon, and by Miss Margaret H. Ferguson. Professor Noël Paton has continued his researches into the relation between the development of the testes and that of the thymus; and Dr. Dingwall Fordyce (now of Liverpool) has carried on his work on the thyroid function in sick children and the effect of thyroid treatment.

Dr. T. Y. Finlay's work on Pirquet's weight and stem length factor should yield useful guides in fixing the measure of normal nutrition at different ages. In all these directions there is plentiful evidence that much good work is being accomplished, and from the results which have already appeared its high value may be gauged. Whilst one would wish for more completed researches and fewer interim reports there can be no doubt that the Medical Research Council is wise in its policy of not attempting to press the research scholars into precipitate publication. Nothing can be less helpful to a piece of investigation than to fix a date for its compulsory termination. The Council is doing a great public service in this as in other respects.

Syphilis.

In the Department of Biochemistry and Pharmacology at the National Institute for Medical Research the routine testing of salvarsan preparations for purity has been continued under the general direction of Dr. Dale. Dr. Burn, Miss Durham and Miss Marchal, members of the staff of the department, have been making a series of estimations of the comparative therapeutic activities of the different salvarsan preparations, and clinical comparisons now being made by Major C. J. White may be expected to show whether the determination of the curative action of salvarsan preparations on mice infected with trypanosomes will furnish an accurate index of the therapeutic value of the preparation in human syphilis. If so it may be possible in due course to add a test for therapeutic efficacy to that which is now made to ensure freedom from abnormal toxicity.

At Oxford Professor Dreyer and Dr. H. K. Ward have devised a new and simple diagnostic test for syphilis, based on the well-known Sachs-Georgi reaction, but differing in the employment of a more stable form of antigen, the sensitivity of which can be standardized. This new "Sigma test" is quantitative, so that its results can be expressed in standard units. This quantitative element, together with the fact that "complement" and red blood corpuscles, which cause so much trouble in the Wassermann test, are eliminated, offers considerable advantages. The new test has been compared with the Wassermann in a long series of cases, and is claimed to be of at least equal diagnostic value. It is intended to arrange an extensive comparative trial of the two tests in a series of cases in different stages of the disease.

Industrial Medicine.

For the financial reasons stated in our first notice of the Medical Research Council's Report (January 14th, p. 76), it was necessary to reorganize the Industrial Fatigue Research Board. The instruction under which the Board now works is to promote investigation into "the relations of hours of

labour and of other conditions of employment, including methods of work, to functions of the human body, having regard both to the preservation of health among the workers and to industrial efficiency; and to advise the Council upon the best means for securing the fullest application of the results of this research work to the needs of industry." Inquiries are now in progress by a number of investigators at different centres into the effects of high temperature, humidity, air movements, and weight-lifting in several industries, including the pottery trade, the cotton industry, linen weaving, and boot and shoe factories. At Glasgow Professor E. P. Cathcart, with the whole-time assistance of Miss E. Bedale, is studying the efficiency of different muscles with special reference to the muscles of women. The services of Miss May Smith, who formerly worked at Oxford with Professor William McDougall on alcohol, have been secured for an investigation of fatigue amongst women workers in laundries, having special reference to arrangement and length of hours, functional periodicity, and general conditions. A committee on the physiology of muscular work has had before it data collected by Dr. H. M. Vernon of temperature, humidity, and other atmospheric conditions in the pottery trade, and by Mr. S. Wyatt of output as correlated with temperature, air movement, and other atmospheric conditions in cotton and flax-weaving factories, special attention being given to questions of ventilation as affecting health and efficiency. The same committee has been considering the report by Professor A. D. Waller and Miss G. de Deckier, who receive a grant from the Council, on the physiological effects of muscular work measured by the exhalation of carbon dioxide. The results have been published by these authors in the BRITISH MEDICAL JOURNAL.

Worms and Mites in Cornish Miners.

In 1902 Haldane and Boycott found that ankylostomiasis was rife in certain Cornish tin mines, and that in particular the underground workers in the Dolcoath mine were heavily and generally infected. Seven years later Dr. Boycott reported that in spite of the introduction of sanitary measures there was little diminution in the incidence of the infection. Owing to the difficulty of securing samples from the underground workers Dr. Boycott had found it desirable to rely on the occurrence of eosinophilia as a more readily applicable method of diagnosis. He held that when eosinophilia exceeded 8 per cent. this might be attributed to *ankylostoma* infections. During the summer of 1920 Dr. R. T. Leiper, of the London School of Tropical Medicine, was commissioned by the Council to investigate the present position, with the assistance of Dr. M. Khalil and Mrs. F. E. Philpott, M.Sc. Dr. Leiper found that a remarkable change had taken place since 1909; of 116 underground workers examined only eight exhibited hookworm ova, and of these only two came from the Dolcoath mine. In one other mine, however, six infected men were found among twenty-two underground workers, but the inquiries here could not be continued as the mine was flooded. Dr. Leiper found that eosinophilia up to 29 per cent. occurred in cases where no *ankylostoma* infection could be detected, but in which other parasitic worms were present.

"Of the total of 130 persons examined, including 14 outside workers at the Dolcoath Mine, 14.6 per cent. harboured *Ascaris lumbricoides*, 14.2 per cent. *Trichocephalus*, 2.3 per cent. *Oxyuris vermicularis*, and 5.4 per cent. *Strongyloides intestinalis*, while in 12 persons—that is, 9.2 per cent.—were found the eggs of mites. These last were determined by Mr. Stanley Hirst, of the British Museum (Natural History), as belonging to *Aleurobius fariarum*, and to species of *Glycyphagus*. These mites commonly occur in wheat, cheese, sugar, and the like, and apparently gain entrance to the body as contamination of food. The adult forms are killed in their passage through the alimentary canal, but the eggs survive and are able to continue their development after leaving the body. As species of *Glycyphagus* give rise to various skin lesions, among which 'grocers' itch' is the best known, it was thought that some etiological association might be found with the 'bunches' or boils which occur in Cornish miners and are attributed to skin infection with hookworm larvae. Experimental efforts to establish this, however, failed."

With material from the hookworm cases Dr. Khalil, working in London, discovered that in fluid media the larvae always moved towards a source of heat. This observation appears to afford a rational explanation for the penetration of the human skin by hookworm larvae, and is not unlikely to provide a simple and good method for the laboratory detection of the larvae of all nematode worms which pierce the skin.

British Medical Journal.

SATURDAY, JANUARY 28TH, 1922.

THE WELFARE WORKER IN FACTORIES AND WORKSHOPS.

OF welfare workers there are several kinds. The variety with which a report issued recently by the Joint University Council for Social Studies is concerned, is the welfare worker employed in factories and workshops. The report begins by pointing out that, although a few well-known firms had appointed welfare workers before the war, especially where many women were employed, it was not until the advent of the Ministry of Munitions that any great development took place. The Health of Munition Workers Committee was set up in September, 1915. The appointment of a welfare supervisor was made obligatory in all national factories, and was pressed by the Ministry on all controlled munition works. The chief difficulty was to find an adequate supply of trained men and women; and the Welfare Department of the Ministry of Munitions endeavoured to assist employers and managers by providing a panel of selected persons. In 1917 a report was issued on courses of training for welfare workers, which forms the basis of the present report. In 1918 a Final Report of the Health of Munition Workers Committee emphasized further the importance of university training for welfare work.]

The Home Office has defined welfare work as "the provision by the management for the workers of the best conditions of employment . . . including everything which bears on the health, safety, and general well-being and efficiency of the worker, while avoiding any interference with his private affairs." To the welfare worker, says the present report, is delegated some part of the function of management; and these definite duties, giving him a recognized place in the internal economy of the factory, form the point of contact between him and the management on the one hand and the workers on the other. Under his supervision come canteens, recreational and educational schemes, medical departments, employment departments, and thrift societies. The isolation of management from workers, which is practically inevitable in large-scale production, is being met by the machinery of the works committees; but the setting up of a works committee does not, says the Committee, solve the problem completely. The whole body of workers must take an interest in its proceedings; a joint committee of the Woolwich Trades and Labour Council and the Woolwich Labour Party states that "Welfare schemes and supervisors must be under a democratic system of control, in which the workers shall have equal participation with the employer." The Joint University Council for Social Studies set out to "equip men and women for posts requiring a wide outlook and some understanding of social theory." The students are divided into three classes: (a) the graduate; (b) the experienced worker with little or no previous academic training; (c) students, matriculated or otherwise, desiring to train for some career for which, given other qualifications, a university degree, though desirable is not necessary—for example, the welfare worker.

The course of training proposed, except in the case of graduates, covers full-time work for two years. The first year is to be devoted to general social study, the

second to specialized training. The curriculum includes industrial and social history, economics, social and political philosophy, health and hygiene, psychology, the outlines of central and local government, elementary statistics, industrial law, business organization, and industrial structure and problems. First-aid training is not considered a proper or possible part of the university course, but it is considered desirable that a certificate should be obtained from another source. The course includes actual participation, under supervision, in various social activities which will "give the candidate some first-hand acquaintance with working-class life." This may be obtained partly by working as an operative in a factory (though exclusive training in factory life is deprecated), and partly by residence in a settlement in a working-class neighbourhood. One member of the Committee felt strongly that every candidate for training should have practical experience in a factory for at least six months or a year, and that this should entail residence in a working-class family, the student supporting herself on her wages. The practical side of the training is to include administration in connexion with health, housing, employment and unemployment, education (adult and continuation), administration of justice, juvenile organizations, and after-care.

From this description of the proposed curriculum it may be gathered that the ideal welfare worker will be a veritable Admirable Crichton in social studies. Knowledge, even in small quantities, is not dangerous provided it is not ill-applied. But it is possible that knowledge, which might be perfectly safe in the hands of the distinguished head of the Ratan Tata Department of Social Science and Administration, might not always be wisely applied by an enthusiastic young welfare worker of two years' university training. No doubt it is essential that the welfare worker should be well-educated and broad-minded, since there is evidence in the report that the post is one needing infinite tact. The most illuminating part of the report is to be found in the appendix, which consists of a memorandum on welfare workers prepared by a joint committee of the Woolwich Trades and Labour Council and the Woolwich Labour Party. The welfare worker in a factory is appointed by the employer. The Home Office defines welfare work as the "provision by the management" of the best conditions of employment. The report of the Joint University Council says, "to the welfare worker is delegated some portion of the function of management." The Labour Party has not yet got over its suspicions of the employer. Hence probably the first condition in the Woolwich memorandum that "welfare supervision must aim primarily at promoting the welfare of the workers, and not at increasing the workers' output."

It is unnecessary to go through the other conditions in the memorandum, involving "democratic control," recognition of trade unions, appointment of welfare workers from amongst the workers, "knowledge of trade union aims and methods," and so on. It is sufficient to draw the inference that highly trained welfare workers paid by the employer are likely to need a great deal of tact, whatever may be their knowledge of social and political philosophy and history. On the employer's side also the university-trained worker will need to walk warily. Excessive zeal in scrapping some sanitary arrangement which does not come up to the particular standard favoured by the university professor may involve the employer in an expense he may not be willing or able to face. Again, there exists already an official charged with certain medical duties in connexion with factories—the certifying factory surgeon. We hope the curriculum of the Joint University Council will include some instruction on the relation of the welfare worker to this medical officer. Lastly, though the Woolwich memorandum suggests that there should be the "maximum of

efficient co-operation between local welfare schemes and the municipality, especially with regard to health, housing, transit, and recreation," it would probably be advisable for the welfare worker to refrain from carrying his beneficent work into the home of the worker.

For the moment the development of the activities of the welfare worker in factories and workshops may seem remote from the work of the ordinary medical practitioner. But although in some directions, such as education, employment, and thrift, the functions of the welfare worker may seem quite apart from medical matters, his or her main duties will be concerned with health. In view of the universal demand for improvement in the health of the community, it is the duty of the medical profession to assert its right to the position to which the training of its members entitles it. The fact that a new form of health worker is being evolved should arouse in medical men more than a passing interest in the report of the Joint University Council.

The first curious fact to be noted is that in a council of thirty-two men and women concerned with university courses in social studies for health workers only two members belong to the medical profession—Dr. Janet Lane-Claydon and Sir Cooper Perry, the latter a co-opted member. Even more surprising is the fact that amongst the twenty members of the committee which made recommendations on a syllabus which includes the subjects of health and hygiene, and psychology, there was not a single medical member. The committee was formed of various distinguished professors of economics and social science, a few manufacturers, some representatives of welfare societies, and one or two Government officials. Whether the Committee took any medical evidence does not appear, but even if it did, we venture to suggest that a committee constituted in the way described would have derived considerable advantage, in a matter which is largely one of health, from the presence of a member possessing medical knowledge. Of the value of educated lay opinion in these matters there can be no doubt, but a balanced judgement is more likely to be obtained when all the essential sides of a proposition are represented. The name of the committee appointed by the Ministry of Munitions, the "Health of Munition Workers Committee," is sufficient evidence that the functions of the welfare workers are largely concerned with health. Moreover, the subject of industrial medicine has developed greatly since the war, and proposals have even been made for the employment of whole-time or part-time medical officers in factories in order to prevent the dissipation of energy by fatigue or ill health.

Whether the Joint University Council's vision of a welfare worker who stands between employer and employed on all sorts of questions materializes or not, we are inclined to think that the relation of this individual to the medical profession will sooner or later become of importance. In the meantime the suggestion has been made in some quarters that many of the proposed functions of the welfare worker can be dealt with better by means of works committees, whereon the employer and the employed can discuss broad questions of welfare and management. The position of a highly trained university welfare worker whose allegiance must be to those who employ him, while he is supposed to represent the grievances and difficulties of the employed, can hardly prove satisfactory. In any case we cannot too strongly insist that so far as health and sanitation go, it is to a medical officer of some kind that the management should look for advice, and not to a welfare worker, however intensive his training. This does not preclude the use of suitable women to supervise the girls employed in factories. Nor does it prevent such matters as recreation and thrift being dealt with by committees of the workpeople themselves, with the assistance of their

employers. The British workman must be sadly devoid of initiative and energy if, with suitable works committees, he is unable to develop methods for providing himself with many of the facilities set forth as coming under the supervision of the welfare worker.

INFLUENZA.

LATE last week the Ministry of Health issued to the press a summary of the information then available with regard to the prevalence of influenza, a statement most of our readers will have seen in the daily papers. Owing to the fact that the mortality figures of the great towns are not available before we go to press, comments on the epidemiological position necessarily refer to data nearly a fortnight old when the JOURNAL is published, but it will be of some interest to notice such features of the epidemic as had been recorded down to the time of writing.

The Ministry of Health expressed the opinion that, in London, the wave was probably at or near its maximum. The purely statistical evidence, imperfect as this is, supports the conclusion. Deaths in London ascribed to influenza in the four weeks from that ending on December 24th numbered 54, 151, 354, 551. If we apply a method by means of which Farr attempted (with some success) to predict the course of epidemics, and determine the constants of the curve of the particular type he sometimes used¹ so as to make it pass close to the four observations, this curve gives 54, 238, 342, 557, as "calculated" values for the weeks in question, 14 for the week ending December 17th, and 678, 616, 417, and 211 for the weeks ending January 21st, January 28th, February 4th, and February 11th. Upon this hypothesis the maximum would occur in the week ending January 21st. But it is evident that the hypothesis is incorrect and probable that it exaggerates the mortality to be expected. This is confirmed by the actual figure for the week—443.

This particular curve is symmetrical, and our experience of influenza is that the epidemic declines more slowly than it rises. A comparison of computed with actual values shows that, to force events into the required shape, the earlier part of the curve must be exaggerated so as to reach 238 "calculated" at the point when only 151 were actually "observed."

Passing from the imperfect statistical information—imperfect because even complete mortality returns are not a satisfactory basis on which to discuss prevalence and the allocation of causes of death can never be scientifically complete—we gather that in hospitals and other institutions in London admissions on account of influenza are decidedly decreasing, an observation which is also favourable to the view that the crest of the wave has been reached.

The Ministry of Health pointed out that the age distribution of deaths in the present recrudescence differed from that of the great pandemic. The relative excess of the oldest age groups which the Ministry noted in the London figures for the week ending January 14th is present, although less emphasized, in the statistics of the 105 great towns where the proportion of deaths at ages over 65 has been rising for three weeks and is now nearly 30 per cent., as compared with less than 10 per cent. in the 1918-19 pandemic. The proportion is indeed very nearly as great as in London in 1891. There is some indication that in the other great towns the proportion of deaths under 5 is appreciably higher than in London. It would be interesting to learn whether any relation exists between a high rate of mortality in childhood (mere returns of deaths at ages without a record of the age distribution of the population at risk are uncertain guides) and the state of nutrition. No doubt the privations imposed by the present condition of

¹ See Farr's *Vital Statistics*, edited by Humphreys, p. 318

trade have varied in severity in different districts, and the relief allowances made by different localities vary.

We have little to add to the information respecting prevalence abroad contained in the Ministry of Health's statement, but we notice in a South German newspaper a telegram, dated January 17th, from Stockholm, asserting that nearly half the inhabitants are more or less stricken by influenza. An earlier telegram in the same journal implied that the numbers of patients removed to hospital in Berlin were beginning to decline at the end of December, while, to judge from local messages, the epidemic was in full progress in the south.

We think there can be no doubt that in this country the disease is generally of a milder type than that which characterized the two later phases of the pandemic of 1918-19. Although it cannot be said that any signs or symptoms have been recorded so far which had not been observed previously, the proportional frequency of particular types is different. Non-catarrhal forms, with a dry and irritating cough, and gastro-intestinal types, sometimes simulating appendicitis, have been more frequent, and the "heliotrope cyanosis" has been much rarer. A good many observers have noted "rashes," in some cases like that of scarlet fever, and lumbago is often mentioned as an early and distressing symptom.

Neither in respect of treatment nor prophylaxis has anything been added to our knowledge within the last few years; the measures recommended in the Ministry's circular, and employed on previous occasions, are still our best means. There is, we believe, a general impression among competent observers, that insufflation of a permanganate solution in normal saline is a much more useful prophylactic than gargling the throat.

On the whole, we see no reason to modify the opinion we expressed a fortnight ago—that this recrudescence is unlikely to attain the dimensions of the third wave of 1918-19, and will be more on the scale of the post-pandemic prevalences of the nineties. We repeat, however, our warning that influenza is terrible on the rebound. What we should like to believe is that the prevalence in the London schools, mentioned in the Ministry's circular, which was noticed towards the end of November and left little trace on the mortality records, was the first wave, and that the present is itself the rebound. But obviously this would not account for the wide dissemination of the disease throughout England. So there remains the small—as we hope and believe, the very small—chance, that after a temporary decline another wave may quickly develop. In our opinion this is an improbable contingency, and we think that the official statement of the case upon which we have commented very justly describes the actual position—namely, that we are experiencing a somewhat severe example of the secondary epidemics which follow in the track of such world storms as shook us in 1918-19.

ART AND MEDICAL SCIENCE.

BERLIOZ—one of the most daring musical minds of his time—was intended by an unimaginative father for the medical profession. There is an apocryphal story that the young man got as far as the dissecting room, and was so horrified at the sight that he incontinently fled and could by no means ever be persuaded to embark on a medical career. Yet if he had, he might have been a happier man, for he would have passed through the fires of self-discipline, and would not have remained, as he did, a moth continually scorching his wings in the flame of life; he would have had the wide experience that was necessary to steady his vision.

It may perhaps be said that it was fortunate that Berlioz abandoned a medical career, for the world might have lost a great artist. This is not really to the point,

for it is certain that he could never have become wholly a doctor. He was temperamentally an artist, and artistic expression was absolutely necessary for his very existence. But it is more than probable that the breadth and stability conferred by a medical education would have helped him better to order his imagination, and conduct his life and work.

There are some artists who, along with the artistic temperament, possess an inherently stable intellect which remains unshaken by the emotional storms that are for ever occurring on the sea of creative energy. Others have not this mental strength, and are at the mercy of external suggestion and chance impulses; they are driven hither and thither by the winds that buffet them. Among musicians Wagner, who harnessed his forces, was of the former type; of the latter was Berlioz, who was their slave.

A scientific training may be very beneficial to an artistic mind by keeping it in contact with the realities, out of which science and art spring. For the measure of the difference between these two great sources of human activity is the divergence in their respective interpretations of natural phenomena. This would be hotly denied by the apostles of unreality and unnaturalness, who have of late occupied the foreground of the transformation scene of art, but who are now receding into their proper place. For them art in relation to natural phenomena is played out, and progress lies along the warped way of the grotesque and pathological. We have suffered them long enough. "Their lean and flashy songs grate on their scannell pipes of wretched straw." The function of the artist is to transfigure, not to distort. To this end science—and especially medical science—may lend him grace. Conversely, it may be held that the possession of artistic susceptibility is inimical to the pursuit of medicine. It may be; but only if uncontrolled. If it is allowed to wander freely and to mix and mingle with the stream of scientific thought, it may become a source of danger. But, kept apart and used on its rightful occasions, it is heaven to the mind.

Mr. Edmund Gosse, in a recent review of the life and work of Mark Akenside, poet and physician, said that he always suspects a doctor of having a half-finished sonnet in his pocket. A pleasant exaggeration, and perhaps a sly dig. Nevertheless, there is no reason why a medical man's work should suffer because his consciousness is occasionally occupied by artistic thoughts. His subconscious thinking continues at least as effectively as if he spent his leisure in any other way. There are some grounds for saying that the practice of medicine is becoming more and more a science and less and less an art. The clinician turns perhaps a little too readily to the laboratory for the solution of his problems, and, when the two differ, it is not always the clinician who is wrong. The rise of the scientific spirit in medicine is one of mankind's finest achievements in progress; no man can foretell what will be the outcome of its growth. But, as long as individual idiosyncrasy exists, the application of scientific methods and results to the human body will continue to be something of an art; demanding, like the other arts, accurate observation, swift intuition, and a catholic understanding.

TESTS FOR COLOUR BLINDNESS IN SEAMEN.

UNTIL comparatively recently candidates for certificates as mates and masters in the mercantile marine, and men working on the railways, were examined for colour blindness by means of pigments of different colours. In the sea service Holmgren's wools were employed, in the railway service the men were asked to distinguish between the colours of dots on a white card. The dot test was employed until quite recently upon the Great Western Railway, and may even now be in use. The North-Western and other railways have for some

years given up pigment tests and used an efficient lantern. The Board of Trade not only prescribed Holmgren's wool test for the examination of officers in the marine, but they also laid down the rule that candidates were not to be asked to name colours, but were to match skeins of wool with three standard, so-called confusion colours. Dr. Edridge-Green and others pointed out that these methods of testing were open to grave objection, in that many who were able to match the colours were in reality dangerously defective in colour perception, while others who failed were not colour blind at all, or at any rate not dangerously so. Dr. Edridge-Green also drew attention to the fact that by none of these tests were men eliminated for whom the red end of the spectrum was shortened. Such men—and there is no doubt that they exist—are unable to perceive a red light of low intensity which is plain to a normal individual. In other words, in a fog at sea they may fail to appreciate a red light which is obvious to the normal sighted. It is only necessary to allude to the fight, long and fierce, waged by Edridge-Green and his supporters with the Board of Trade. Step by step, in face of bitter opposition from officials, from physicians, and from some physiologists and ophthalmologists who might have been expected to know better, ground was gained, although the Board of Trade were supported by the Royal Society, till eventually a committee was formed to examine the whole question. As a result of its report, a lantern was used in the examination side by side with the now obsolete wools. The battle was all but won. The final victory coincided with the appointment of Dr. Edridge-Green as Adviser to the Board of Trade on colour vision and eyesight. Dr. Edridge-Green has just issued his report, which lies before us. It is agreed that anyone who can distinguish between red, green, and white lights at a distance of a mile has sufficiently good colour perception for navigation. Edridge-Green states that 25 per cent. of men have diminished colour perception, and that 5 per cent. will fail to differentiate red, green, and white lights, in a properly constructed lantern, or the actual lights themselves, at a distance of one mile. We gather that, in the opinion of Edridge-Green, men who fail with the lantern are to be held dangerous at sea, and those who pass the lantern test are safe, and this no matter what degree of abnormality in colour perception they may show with other tests. He says definitely that the possession of a sense of yellow is a sure indication of safe colour vision. There are many who will not agree with that portion of the report which deals with the Edridge-Green theory of colour blindness. In the main it may be true, but there are some anomalous cases which the theory fails to explain. As regards the tests we are on surer ground. The men have to name colours shown in a ship's sidelights or from shore lights. It is not part of their duties to match wools. Common sense demands that if the men have to distinguish lantern colours they shall be examined with a lantern. This will in future be done. The Board of Trade will come into line with the Royal Navy and the more enlightened railway companies, and will test its candidates for the work they have to do, and as far as possible under conditions similar to those which obtain at sea.

THE PLAGUE IN SHAKESPEARE'S LONDON.

It is not always realized that there were several outbreaks of plague in London before the Great Plague of 1665, and that each of them in its turn was called great. The outbreaks of 1592-93 and 1603 were described by Dr. F. P. Wilson, lecturer in English at Oxford University, in an address to the History of Medicine Section of the Royal Society of Medicine on January 18th. Among other details he gave a list of the prophylactics which were recommended by the wiseacres of the time. These included the chewing of lemon rind, which it was suggested later in the discussion might have had a scientific basis, for the essential oils of lemon rind are antiseptic. Another procedure was to fumigate rooms by sprinkling vinegar on a red-hot brick; great faith was placed in pecked onions, the idea being that they

would gather to themselves all the infection in the neighbourhood. Treacle was taken internally, and the smoking tobacco was regarded by some as a rare antidote; other advised a more drastic safeguard in the shape of a draught composed of sack, salad oil, and gunpowder, which, by causing vomiting, expelled any incipient infection. By the writers of the period the plague was ascribed commonly to any of four causes. The first was supernatural, the outbreak being regarded as divine punishment for sin; the second was the corruption of the air. The author of *Timon of Athens* whether Shakespeare or another, coupled these causes:

When Jove
Will o'er some high-iced city hang his poison
In the sick air.

The third cause was planetary influences; in 1603, for example, astrologers noted that Saturn and Jupiter were conjunction in Sagittarius. The fourth cause was derangement of the body humours, and treatment differed according to these humours; thus, the sanguine man was bled, and the choleric purged with rhubarb, but it was added that all treatment must be "under the direction of a learned and diligent physician, and not according to the fancy of foolish chymic women." As in many other cases, doctrines false in the selves resulted in excellent hygienic measures. Thus the idea that the air was corrupt caused certain sanitary precautions to be taken, and the idea that the plague was encouraged by body humours led to attention being paid to diet. The plague orders of 1603 showed that the dog was regarded as a carrier; it is an irony that suspicion should have fallen upon the enemy of the rat. The orders forbade the attendance of crowds at burials, fixed the fees of profiteer sextons, and warned the public against unsound and especially tainted fish and musty corn. Before the sixteenth century there had been no attempt to isolate the infected but in 1518 infected houses were ordered to be marked by a special sign, and by 1603 the sign was a red cross and usually the inscription "Lord have mercy upon us!" was added. To this practice Shakespeare refers in *Love's Labour's Lost*. The plague of 1603 reached its height at the end of September, when 3,000 people died in London in a week. Unhappily, when the epidemic became really virulent, the populace got out of control, and the authorities had to sit with folded hands. Many magistrates and others left the town, did a number of physicians, whose desertion earned the bitter comments of the satirists. But others stayed, including Dr. Thomas Lodge, who in 1603 wrote from Warwick *A Treatise of the Plague, containing the Notes, Signs, Accidents of the Same, with the certaine and absolute Cures, Fevers, Boles, and Carbuncles that reigne in these times*. In the brief discussion following the lecture Dr. F. Crookshank quoted from this book to show that even before an outbreak rats, mice, and moles left their underground homes and died in large numbers. Dr. F. W. C. suggested that the whole of the mortality in these plague years may not have been due to plague; possibly influenza, typhus, and later in the seventeenth century small-pox, took their toll.

MEDICAL MORTALITY IN AMERICA.

It is estimated by the *Journal of the American Medical Association* that 2,343 medical practitioners died in United States and Canada during 1921. This, on an estimate of a total of 160,000 practitioners in those countries, is equivalent to an annual death rate of 14.65 per 1,000. The age stated in 2,118 cases; 29 were under 30, 160 between 31 and 40, 298 between 41 and 50, 409 between 51 and 60, between 61 and 70, 393 between 71 and 80, 240 between 81 and 90, 17 between 91 and 100, and one lived to the age 101. The greatest number of deaths for a given age occurred at 66, at which age 71 deaths were recorded. Of the 2 known causes of death 426 were from diseases of the heart and circulatory system, 128 were from carcinoma and coma, 196 from cerebral haemorrhage, 167 from pneumonia, 79 from chronic nephritis, 47 from tuberculosis, and 32 from

appendicitis. Ninety-seven deaths were stated to be accidental; 41 were caused by automobile accidents, and of these 22 occurred at railway level crossings; firearm accidents accounted for 17 deaths, railway and tramway accidents for 14, and drowning for 6. Nineteen deaths were due to homicide, all caused by firearms, while, *horrible dictu*, one medical man was electrocuted on conviction of the murder of his wife. There were 69 medical deaths from suicide—29 by poison, 19 by firearms, 7 by jumping from high places, 5 by cutting instruments, 4 by drowning, 3 by asphyxiation, and 2 by strangulation.

MAN AND THE LOUSE.

In his short monograph on *The Louse as a Menace to Man*,¹ issued by the Natural History Department of the British Museum, Dr. James Waterston gives a straightforward account of the life-histories of the three forms of lice which prey on man, and describes methods for their destruction. He insists that the essential factor in the spread of lice is a person who is already infested by the parasites, and, as a rule, transference to a clean person is effected by contact of a more or less direct kind. Contact has long been recognized as the determining condition of dissemination in the case of the crab-louse, but it is no less true of head and body lice, in regard to whose spread many misconceptions are prevalent among the lay population. The importance of close association between clean and infested persons in spreading these pests was abundantly demonstrated in the late war, when men were crowded for long periods in dug-outs and billots, or herded together in prison camps. The normal activity of both head and body lice is found to be greater than was commonly supposed, and this is responsible for their spread; but, in certain circumstances—temperature being the decisive condition—lice will leave their host without the stimulus afforded by contact with the fresh victim. Broadly speaking, says Dr. Waterston, body lice tend to leave a host whose temperature rises above, or falls below, the normal; they are stirred to activity by violent exercise on the part of their host, and in cases of fever will be found moving on the upper blankets. Similarly after the host's death lice appear, sometimes in enormous numbers, while the body is cooling and migrate to surrounding bodies. Typhus fever, relapsing fever, and trench fever are, of course, well known to be spread by lice, while *Bacillus pestis* has also been found in lice feeding on plague patients. There is no evidence, however, that lice are of importance in spreading this disease, although in Dr. Waterston's opinion there is reason to believe that they might on occasion do so. In regard to the destruction of lice, he recommends, for lice on the body, smearing the skin thickly with undiluted paraffin emulsion, followed by a hot bath and clean clothing. In cleansing the head he recommends paraffin oil (preferably) or its emulsion, rubbed in thoroughly, the head being afterwards swathed in a tightly wrapped towel for an hour. Mr. A. Baeot found wood tar oils effective. Mr. Burt Hamilton recently, however, pointed out in one column that the one essential to safety in any mixture that is to be prescribed for home use is non-inflammability, owing to the ingrained carelessness of the class for which such treatment is usually required; he considered paraffin effective for institutional use, but refused to prescribe so dangerous a method for home use. The question of a suitable mixture for this purpose, which should be cheap, non-inflammable, and harmless to the skin and hair, is one which merits further study.

INDUSTRIAL FATIGUE AND MOTION STUDY.

In Report No. 14 of the Industrial Fatigue Research Board Mr. Eric Farmer gives a critical summary of the chief observations made by Taylor, Gilbreth, and others on what is generally known as "Time and Motion Study," and the methods of industrial work which they instituted as the result

of these observations. Taylor's main object was to obtain a better output from the worker, without much regard to his fatigue. In fact, he stated quite frankly that "all employees should bear in mind that each shop exists, first, last, and all the time, for the purpose of paying dividends to its owners." His method was to divide the work into its various elements and time them separately. The results were then summed and a certain percentage added for unavoidable delays. He chose his best workmen for time study, and induced them to work as fast as possible by increased remuneration. Finally, a standard "task" was set, which required the workman "to do between three and a half and four times as much work in a day as had been done in the past on an average." Gilbreth endeavoured to attain the same objects as Taylor—namely, the standardization of the human element in industry—but he not only standardized the time for doing a task, but the method of doing it. He took the time required by various expert workmen to perform the constituent parts of an industrial operation, and found that some men were quickest at one stage, others at another. He selected the quickest timings from the various men, and combined them to form a standard which represented the shortest possible time that the operation could be completed in. Hence Gilbreth regarded the quickest movement as the best, and he even goes so far as to say that in teaching a new movement speed must be insisted on from the very first. He regards it as more important to get speed than to get accuracy of movement or quality of work. His reason for adopting this point of view is that the path a movement follows is different when the movement is done quickly than when slowly. Mr. Farmer, in criticizing these methods, maintains that the quickest movement is by no means always the best for a worker to accustom himself to. Owing to its inherent difficulty it may cause too great a nervous strain and fatigue him unduly. He considers the underlying principle of motion study to be rhythm and not speed. The best set of movements is the easiest set and not the quickest set. The efforts of the investigator should be concentrated on increasing the ease with which an industrial operation can be performed, thereby lessening fatigue. He should not worry about increased production, though in actual practice it was found invariably that when a proper system was carried out the production went up. For instance, in sweet dipping, when an almond or other centre is placed in a basin of melted sugar and, after being coated, is placed on a tray, most of the workers performed the operation by moving the hand in straight lines first in one direction and then in another, but by getting them to move the hand in curves, without any sudden changes of direction, they performed the operation more smoothly and easily, and soon increased their output considerably. By the application of somewhat similar methods to the process of packing sweets in bottles the output was increased 50 per cent. When applied to the packing of chocolates in boxes it was increased 38 per cent. Even more striking results than these have been obtained by Mr. Farmer in a metal trade.

THE DETERMINATION OF SEX.

At the Royal Society of Arts, on January 18th, Mr. Julian S. Huxley, M.A., of Oxford, read a paper on the biological theory of sex. After recalling some of the facts recently ascertained, he said that some twenty years ago American observers had noticed that the chromosomes of various insects differed in the two sexes, the male having one less than the female. Later work had shown that there was a similar sexual difference in the chromosomes of a large number of animals, and it was evident that sex control would be possible if any means could be discovered of influencing the behaviour of the chromosome by causing it more often than usual to stay in the egg and play a part in the embryo. In moths this had actually been achieved. It had yet to be explained, however, how variation in chromosome mechanism in the early stages of development was translated through complex processes into adult sex differences. He gave an account of some very interesting work, as yet unpublished, by Dr. Crew on fowls. It was established

¹*The Louse as a Menace to Man*. By J. Waterston, B.D., D.Sc. London: Printed by order of the Trustees of the British Museum, and sold at the British Museum (Natural History), and by R. Quaritch, Ltd. and Dulau and Co., Ltd. 1921. Demy 8vo, pp. 20; 4 figures. 6d.]

that changes in metabolism in the delicately adjusted internal environment of higher animals might produce profound alterations in sexual characters. It was possible that substances might be found whose injection, even into the adult organism, might bring about sex change. The only evidence that large changes in sex ratio might be brought about in man was afforded by the recent and as yet unconfirmed work of Siegel, based on statistics collected during the war concerning children conceived when their fathers were home on leave for short periods, and was held to show correlation between the probable sex of the offspring and the time during the menstrual cycle at which impregnation and fertilization occurred. It had to be remembered, of course, that very little certainty had yet been reached as to the exact time during that cycle at which the ovum was liberated. If these statistical results corresponded to reality, the way would be open to a large measure of human sex control, which, if not properly directed, might bring about the most revolutionary social changes. The lecturer touched on partial sex reversal, leading to the production of intersexes, usually referred to in medical literature as pseudo-hermaphrodites; he thought it probable that maladjusted sex factors might exist in man even as in moths. If human sexual abnormality were considered in the light of recent work on animals, there seemed to be a distinct theoretical possibility that cases of sexual perversion might be cured by injection or grafting of the proper reproductive organ, a procedure which was being tested in Germany. It was highly probable that human intersexes were neither male nor female, but definitely intermediate, and, if so, it must be wrong to assign a normal sex to them legally. Departures from sexual normality were visited with legal pains and moral censure, but if many who thus departed from the normal were simply in the grip of blind hereditary forces, it was clear that a new standard was needed to measure what was now called moral perversion. In conclusion, Mr. Huxley pleaded for a fuller appreciation of the science of pure biology. The tendency at present was for medical research to become more and more biological; but this might induce biology to become more and more medical, which he considered would be dangerous. The medical point of view must naturally be dominated by the study of human and mammalian physiology, while pure biology, busy with nature's myriad types, would be continually discovering more favourable material and new points of view. Dr. P. Chalmers Mitchell, F.R.S., secretary of the Zoological Society of London, who presided, said that in so fundamental a thing as sex, which went right back to the lowest organisms, he would be rather surprised to find different ways of determination. He thought it difficult to believe, for instance, that birds or moths determined through the female and mammals through the male. He would expect to find the same laws operating throughout the animal kingdom. It appeared that the primary distinction of sex was determined at fertilization, and the mechanism was adjusted so that under normal conditions there would be an equal proportion of males and females; although Mr. Huxley had shown that this ratio could be altered experimentally in certain cases, there was a very great difference between primary and secondary sexual characters. He hoped the audience would not go away with the idea that because certain discoveries had been made regarding moths, the world would be revolutionized or even that the criminal law would be amended.

THE HISTORY OF CHEMISTRY.

A GALLERY has been set apart at the Wellcome Historical Medical Museum to illustrate the history of chemistry, from the most primitive use of still and furnace to the exact and elaborate methods of the present day. It has been arranged in such a manner as not merely to interest or even instruct the casual visitor but to inspire the student, and to furnish, so far as this can be done by pictures, manuscripts, and models, a graphic outline of the progress of chemistry through the ages, not forgetting the cloud of magic and superstition out of which it emerged. On the pillars and frieze the

student is reminded of the epochs into which the history of chemistry may be divided, the names of its pioneers, and the symbolism which has been employed by ancients and moderns. At one end of the gallery there is placarded the definition of chemistry which appears in Johnson's Dictionary, and at the other the definition which appears in Murray's. The objects in the collection include examples of ancient glass apparatus employed by the alchemists; these include matrasses, cucurbits, alembics, and the like. A model of the alchemist's hearth, with its pewter and stoneware, has been installed, as well as the "aludel" of the sixteenth century, used for subliming sulphur or mercury, and, in curiously shaped bottles, specimens of the elements and their symbols as they were known at this period. A most interesting section illustrates the history of perfumes and aromatic substances. The curator has gathered together many specimens of the little containers in which, from Roman times onwards, mixtures of substances of powerful odour have been carried in the hope of warding off plague and other infections. In another cabinet there is a collection of the chemical substances known in ancient times, together with specimens of alkaloids, with the names of those who isolated them, and the date of their introduction so far as these can be ascertained. Other articles, in original or replica, have an interest on account of a particular individual; these include appliances used by Dalton and Faraday in their demonstrations, the pneumatic trough used by Priestley for collecting gases, a porcelain retort which belonged to Joseph Black the discoverer of carbonic acid, old books on chemistry which had been in the possession of the Boyle family, and documents in the handwriting of Caventon, one of the discoverers of quinine, and Labarraque, whose name is associated with the manufacture of sodium carbonate. On the walls of the gallery are carefully chosen pictures, in oil and water-colour, representing personalities and episodes of interest to chemists. Such primary figures are depicted as the Greek Hermes, the Arabian Rhazes, and the German Paracelsus, who insisted that the function of chemistry was not to make gold artificially, but to prepare medicines and substances useful to the arts. The various alchemical processes used in the search for the "philosopher's stone" are depicted on long scrolls by a fifteenth century draughtsman, and there are many paintings of the Dutch and Italian schools, whose artists appreciated the pictorial value of the alchemist in his laboratory, lighted by lurid flames and heaped up with strange accessories, though their rendering may not always have been quite faithful. One interesting portrait is that of Mayow, the father of pneumatic chemistry, who was originally a physician; the visitor is reminded in the same way of Lavoisier, and of Scheele, to whom we owe glycerin and prussic acid; of Dalton, Humphry Davy, and Liebig, and many others. The gallery is dominated by the statue of Joseph Priestley, the discoverer of oxygen and nitric and nitrous oxide.

A SURGICAL TOUR IN THE UNITED STATES AND CANADA.

WE are indebted to Lieut.-Colonel Henry Smith, C.I.E., who has recently retired from the Indian Medical Service, for the following note of his American tour. The Ohio State Medical Association asked me to address their annual meeting in May last, and arranged a tour for me over the North American continent to discuss and demonstrate the treatment of cataract. Though I was not in America on any official footing, the reception I met with was overwhelming. The American War Office put an aeroplane at my disposal, and my American friends arranged for me to see their President. Through the names of Dr. Vail of Cincinnati and of Dr. Meding of New York I wish to thank all those who co-operated with them in giving me hospitality and the opportunity of demonstrating intracapsular extraction of cataract. The arrangements made were perfect, and must have given those concerned an enormous amount of trouble. It was well known that I was not satisfied with the older operations for cataract and after cataract. The American

and Canadian surgeons wished to discuss these matters with me personally and informally in all their aspects. As I have had experience of every variety and every complication in quantity, I was able to give them definite opinions with my reasons for them. At first I was unwilling to operate as I had not my trained assistant, nor would the cases be under my care after operation. So much pressure was put upon me, however, that I consented. Many of the clinics had thus to be raised at short notice, but despite this the material put at my disposal was ample, the clinics ranging from 20 to 78 cataracts. Altogether I operated on over 500 cataracts together with many cases of other intraocular conditions requiring operation. A large proportion of these cases were complicated, and had been already turned down as inoperable—such as cataracts with the iris tied down to the lens all round, night blindness, choroidal degeneration, etc. These cases were much more interesting to the American surgeon than the normal cataract. They were second and third class risks, but I did not object to do them so long as the patient and his surgeon recognized the risks. With the experience I have had I was able to estimate the risks closely, and thus was able to operate with a small percentage of failures. In normal cases I had practically no failures. The American surgeon was interested to learn that cases complicated with night blindness were as good a surgical risk as any other. The cases which interested me most were those of cataract where the other eye had been operated on by the capsulotomy method; all left something—many of them much—to be desired. After seeing these I felt that I had previously been overestimating the merits of the capsulotomy method. From the magnitude of the cataract clinics raised for me at short notice one would think that cataract was prevalent in the United States of America as it is in the Punjab (78 cataracts in one day, for instance). This is not so; it is no more prevalent than in the British Isles. I doubt if America has ever before seen a clinic of 30 cataracts in one day. These clinics and the number who co-operated in raising them prove that the American is not satisfied with the results of the capsulotomy method. The American surgeon stands in the front rank of the surgeons of the world (and he finds that many cataract patients refuse capsulotomy operation because they do not think it worth while). He has no school. The world is his school. He is ready to scrap his machinery the moment he finds someone else has got better. The old world has to look to the new world for the spirit of advance. Another interesting advance was Dr. Lister's ophthalmic school in Chicago, of which I hope to write an account elsewhere. In conclusion, I cannot say how much I appreciate the reception given me by both the general and ophthalmic surgeon in the United States and Canada.

POST-GRADUATE INSTRUCTION IN LONDON.

To consider the needs for medical practitioners in South-West London for post-graduate instruction a committee has been formed of representatives of the Wandsworth Division of the British Medical Association, the South-West London Medical Society, and the medical staff of the Bolingbroke Hospital. Under the auspices of this committee a post-graduate association has been formed, and courses of instruction are being started in connexion with the Bolingbroke Hospital and the St. James's Municipal Hospital; the latter has 750 beds, and has now twelve consultants attached to it. It is intended that members of the South-West London Post-graduate Association should have facilities for attending the practice of those hospitals, and the inaugural address of the course will be delivered on Wednesday, February 1st, at 4.30 p.m., at St. James's Municipal Hospital, Onseley Road, Ballham, by Sir Almroth Wright, K.B.E., F.R.S. All medical practitioners in South-West London are invited to this inaugural meeting; tea will be served at 4 p.m. The idea of carrying on post-graduate instruction in a well equipped municipal (formerly Poor Law) hospital in a suburban district, linked up with a neighbouring general hospital, is an excellent one. The general practitioners in the district will find it very much easier to attend a post-graduate course that is brought,

as it were, to their doors than to spend an hour or more getting to the hospital where the course is being conducted. Similar courses might well be started by the consultant staffs of municipal hospitals in other London suburban areas. The provision of post-graduate instruction in the heart of London continues to occupy the attention of other hospitals. During the past year the medical staff of the Central London Throat and Ear Hospital has introduced several new features into its course of instruction for post-graduate and senior students. In December last a special intensive course of eight lectures and demonstrations was given, and this was very largely attended. Another innovation has been the introduction of a consultation afternoon once a month; at these meetings cases are shown and discussed by the members of the staff.

SIR PATRICK MANSON.

A PORTRAIT of Sir Patrick Manson was unveiled on January 20th at the London School of Tropical Medicine by Sir James Michelli, C.M.G. The portrait was subscribed for by a large number of past and present students of the School and other friends of Sir Patrick Manson at home and abroad. It has been executed by Mr. E. Webster, and suitably reproduces the characteristic features and genial expression of the founder of the School. It has been hung in the vestibule, where it will be seen by everyone entering the building. Reproductions are being made by Mr. Malcolm Osborn and will soon be ready. Money has also been subscribed for a medal in recognition of Sir Patrick Manson's services as a clinician. It will bear a portrait of Sir Patrick by Mr. John Pinches, and will be awarded annually to those who distinguish themselves in clinical work. The presentation of the portrait was acknowledged by Sir Patrick Manson himself, and among those present at the ceremony were Admiral of the Fleet Sir Henry Jackson, G.C.B., F.R.S., Surgeon Rear Admiral Sir Percy Bassett-Smith, K.C.B., Major-General Sir William Leishman, K.C.M.G., F.R.S., Major-General Sir Thomas Yarr, K.C.M.G., Sir Leonard Rogers, C.I.E., F.R.S., Dr. J. B. Christopherson, C.B.E., Dr. Andrew Balfour, C.B., Dr. A. G. Bagshaw, C.M.G., Director of the Bureau of Tropical Diseases, and many members of the staff of the Tropical School.

INTERNATIONAL SOCIETY OF THE HISTORY OF MEDICINE.

A MEETING of the permanent committee of this society was held at the Faculty of Medicine in Paris on January 7th. Professor Menetrier (France) presided in the absence of Dr. Tricot-Royer (Belgium). There was a large attendance of delegates, including those from Belgium, Denmark, France, Great Britain, Holland, Norway, Poland, and Switzerland. The statutes of the society were considered and adopted. It was decided that the society should meet in congress in London on July 17th to 22nd next, and afterwards every three years in any town selected by the general assembly. The subscriptions for membership of the society, including the congress, were fixed at 40 francs; for membership of the congress in London only, 50 francs; and for students, associates, and relations of members, 10 francs. Subscriptions from countries other than France were to be paid in the equivalent value in the nation's coinage independently of the exchange. For England the subscriptions will be as follows: For members of the International Society, including annual subscription, £1 12s.; for members of the London Congress only, £2; and for associates, students, and relations of members, 8s. Members of the society and those joining for the congress will be entitled to receive a copy of *Liber Memorialis*, or volume of the proceedings, which will be published after the meeting. The forthcoming congress in London, the headquarters of which will be the Royal Society of Medicine, will, it is hoped, be interesting, and a large attendance is anticipated. Papers will be read on the history of medicine in all its branches. A programme of the meetings and entertainments connected with the congress will be issued shortly. All communications should be addressed to the general secretary, Dr. J. D. Rolleston, 21, Alexandria Mansions, King's Road, London, S.W.3.

Paris.

(From our Correspondent.)

FEE-PAYING HOSPITAL PATIENTS.

I HAVE already mentioned the revolution quietly brought about in the method of recruiting the medical staff of the Paris hospitals, but a movement even more revolutionary from the social point of view is going on in the method of recruiting hospital patients. Nothing is changed in the principle to which the hospital owes its name; the poor are still admitted as freely as ever, but our hospitals are no longer gratuitous. Strange abuses have come to light. In the consultations for minor ailments many persons have presented themselves, glad to benefit by the advice of a leading consultant, but disinclined to put themselves to the cost of even saying "Thank you." Others have unblushingly obtained admission to the surgical clinics or the maternity wards. This scandal at length caused the professional associations to take the matter up, and new regulations have now been made. Henceforth our hospitals are to be free only to patients found after inquiry to be really poor.

In practice, every patient who presents himself at an outpatient department is examined, and it is only on his second attendance that inquiry is made. This plan is followed in order that urgent cases may not be refused. The fee for consultation varies, but is never more than five francs. A hospital day brings in about twenty francs in the surgical department. This money is turned over to the funds of the Assistance Publique, and the medical staff receive nothing. Thus, our hospitals in Paris tend to become in part private hospitals at reduced prices, to the great advantage of a class otherwise too rich for the hospitals and too poor for the nursing homes. What, then, it will be asked, is the position of the medical staff? The *clientèle* they lose on the one side is not given back to them on any other; once again the medical man is to sacrifice himself for humanity, an attitude the nobility of which is recognized by everybody except the tax collector! Again, will not medical teaching suffer? The great specialist consultations, such as those at La Salpêtrière and at the St. Louis, live, so to say, on the immense number of patients who apply; from among them it is possible constantly to keep in touch with some that serve as illustration of a rare syndrome. Shall we not see this source dry up, and will not a number of interesting cases prefer private life to the payment of fees?

This same question arises in provincial towns where the medical staffs show a disposition to transform the hospitals into nursing homes, and where they do not pretend always to give their time, experience, and responsibility *gratis pro Deo*. It must be recognized that in this new after-the-war world actual pauperism is tending to disappear. It is only the disabled and the old who cannot make their own living. A good pair of arms is worth more than a diploma. Everything commands its price. The value of intellectual work only is at the lowest level. Thus, the discussion is carried on between those who look upon medicine as a priesthood and those who hold it to be an occupation by which a man may live.

The priest, it is said, lives by the altar, and there are many of us who ask if our scientific world does not push generosity to a point where the term ceases to be applicable. The example of Pasteur is typical, the commercial development of his discoveries would have endowed his institute more royally than could any Rockefeller. Fortunes have been built up by speculators who have exploited such disinterestedness. In France antidiphtherial serum is sold, on presentation of a medical prescription, by all pharmaceutical chemists, who keep it always in stock and sell it at cost price. In addition local authorities and hospitals supply it gratuitously. Is this a logical procedure? Should not Plutus be invited to recognize generously the value of the life of his child? On the other hand, it is true that we salute with enthusiastic esteem that apostle of antitoxic treatment, Dr. Roux, of whom it may truly be said that he made himself poor for us.

THE FEMINIST QUESTION.

The feminist question has come up again in connexion with the proposal to elect Madame Curie to the Academy of Medicine. It may be recalled that her candidature was turned down before the war by the Academy of Sciences. I ought, perhaps, to say that the Academy of Sciences is one of the five academies which constitute the Institute of

France, while the Academy of Medicine is an independent society not attached to the Institute. It includes 100 titular members representing the medical and allied sciences; not all belong to the medical profession. The scientific fame of Madame Curie is such that an academy would honour itself by electing her. There is no objection, then, to her as an individual. It is simply the principle which is in question. There is no doubt that our academies will eventually open their doors to women, but the fruit is not yet ripe. It is a curious thing, but the only systematic opposition to Madame Curie that I have come across is on the part of a lady whose salon may be described as an antechamber of the Institute; "The election of Madame Curie would create a precedent of which Madame X. Y. Z. would take advantage to enter the Académie Française—and that would be scandalous." At the beginning of this letter I spoke of the revolution which has taken place in our minds after the war. As you may now see, I exaggerated!

Yet the times are new. The military school of public health in Paris has just opened its doors to civilian medical men and students; they may all make use of the library, museum, lectures, and laboratories. In order to obtain admission foreign medical practitioners must address a request to the Minister of War.

England and Wales.

MEMORIAL TO PROFESSOR DELÉPINE.

It is proposed to place a bronze memorial tablet to Professor Sheridan Delépine in the Public Health Laboratory at Manchester, and old pupils and friends have been invited to subscribe sums not exceeding one guinea. In connexion with the matter a committee has been formed, including Sir Henry Miers, Vice-Chancellor of Manchester University; Sir Edward Donner, Dr. Niven, Medical Officer of Health of Manchester; Dr. Brindley, Dr. Slater, Mr. Heap, and Dr. Sidebotham. Contributions should be sent to Dr. E. J. Sidebotham, Public Health Laboratory, York Place, Manchester.

ROYAL SANITARY INSTITUTE.

The thirty-third congress and exhibition of the Royal Sanitary Institute will be held at Bournemouth from July 24th to 29th, under the presidency of the Right Hon. J. E. B. Seely, M.P. A preliminary public meeting to inaugurate the organization of the local arrangements was held at the Town Hall, Bournemouth, on January 12th. The introductory lecture to the spring courses of lectures will be delivered at the Institute, 19, Buckingham Palace Road, S.W., by Professor H. R. Kenwood, on January 30th, at 5.30 p.m. A course for sanitary officers will begin on February 1st, and will be in two parts, the fee for the complete course being 5 guineas. Practical training for meat and food inspectors will commence on February 10th, and will be held over two months, the fee, including lectures and demonstrations of Part II of the course for sanitary officers, being 5 guineas, or, without Part II, £4 14s. 6d. A course for women health visitors and child welfare workers will commence on February 3rd, and will be in line with the course of training which has been set out by the Board of Education. The fee for the complete course of lectures and demonstrations is 5 guineas. Forms of application and full particulars of the courses can be obtained from the secretary.

Scotland.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.

At a meeting of the Aberdeen Medico-Chirurgical Society held on January 19th Dr. Scott Riddell, the President of the Society, made feeling reference to the deaths of Dr. G. M. Edmond and of Dr. W. R. Pirie. He said that during the last few weeks the hand of death had been laid very heavily on the society, and it was fitting that they should place on record their sense of personal loss and their deep regret at the passing of two of the senior members, Dr. George Maitland Edmond and Dr. William Rattray Pirie. The traditions of medical skill, of professional rectitude, and of devotion to the service of suffering humanity, had always stood high in Aberdeen, and these colleagues whom they

mourned nobly upheld these traditions. But the loss was more than personal to his colleagues; it was felt by the community, by the medical profession in the North of Scotland, and by past and present students of the medical school. Dr. Edmund and Dr. Pirie, as teachers of clinical medicine at the Aberdeen Royal Infirmary, had left their impress on a generation of its graduates, and their names would long be held in affectionate remembrance by many old students at home or abroad. "Our colleagues," Dr. Scott Riddell concluded, "have passed to their rest, full of years of honourable service. They were 'good and faithful servants' of the public and of the profession. 'Si monumentum requiris,' it will be found in the fragrant memories of their full and fruitful lives, which are enshrined in the hearts of many grateful patients and many sorrowing friends. The loss to the medical profession and the medical school is deplored by the members of this society, who had such ample opportunities of appreciating their professional skill, their devotion to duty, and their worth and worthiness as men."

HEALTH OF SCHOOL CHILDREN IN GLASGOW.

In the annual report on the medical inspection and treatment of school children issued by the education authority of Glasgow, Dr. E. T. Roberts states that the statistics confirm the constant improvement in respect of cleanliness and skin conditions since the institution of medical inspection. An improvement in the clothing of the children was also noted, except in the case of footwear. The amount of treatment carried out in the authority's clinics during the year shows an increase in all departments except in that of diseases of the eye. The most striking growth, however, was less in the number of cases treated than in the number of attendances made by these cases. This increase was due to the additional days upon which attendance was possible, and to the improved organization for reporting attendances, absences, etc., between schools, clinics, and attendance officers. The number of ear cases was practically the same as for the previous year, but the number of attendances showed a large increase.

Ireland.

MEMORIAL TO DR. JAMES LITTLE.

A BRONZE plaque bearing a portrait in bas-relief, the work of Mr. Oliver Sheppard, R.H.A., has been erected in the hall of the Royal College of Physicians, Kildaro Street, Dublin, in memory of the late Dr. James Little, ex-President of the College, who died in December, 1916. The memorial was presented by the Fellows of the Royal College of Physicians of Ireland, and the ceremony of unveiling took place on January 17th, in the presence of a large and distinguished company, with the President of the College, Sir James Craig, in the chair. Dr. Walter G. Smith, in asking the College to accept the memorial of their ex-president, referred to his intimate association of fifty years with Dr. Little. He could never forget his unvarying kindness and his fostering help to the young aspirant in medicine. Dr. Little was born in Newry, and carried with him through life the impress of his northern nationality. Attracted by the lure of Dublin he forsook his country practice, and came up to town to try his fortune. His appointment as physician to the Adelaide Hospital laid the foundations of his future success. For sixteen years he was Regius Professor of Physic in the University of Dublin, and he was one of the founders of the Dublin (late Leinster) Branch of the British Medical Association. He was appointed Crown nominee on the General Medical Council, and for nineteen years he remained a member of the Council, in the proceedings of which he took a very active share. He was warmly attached to the Royal College of Physicians of Ireland, and received from it every possible token of honour or office. For two years he zealously and courteously filled the responsible and sometimes trying post of registrar of the College. He reigned as President for two years, and steered its course with unflinching dignity, generous hospitality, and consummate tact. He married at the age of 35 and had two sons and a daughter, who survived him. During a long and active life Dr. Little gained the esteem and affection of an immense circle of friends and patients, and his memory would ever be cherished by those who knew him. The Provost of Trinity spoke of the respect and esteem in which Trinity College had ever held its professor of physio, and said that Dr. Little was a good man as well as a great physician.

Correspondence.

CERTAIN ASPECTS OF PAIN.

SIR,—I read with much interest Dr. Henry Head's address on "Certain aspects of pain." Thirty years ago I published the records of my first attempts in the study of pain, Dr. Head following shortly after. He pursued his investigations by tracing the paths into the nerve trunks, spinal cord and brain, and we all admire the brilliant results he achieved. His address, however, reveals that he is not aware of the great progress that has been made in the study of the subject at the periphery, for I find in his paper all his references are based on cases recorded more than a quarter of a century ago.

Records made in the early stages of an investigation with imperfect methods should be discarded when the methods have improved, and the views based upon these imperfect records should be submitted to a rigorous re-examination.

It was in 1891 I discovered that cutaneous hyperalgesia was frequently present in disease of the viscera. At the time I vaguely realized that in this sign we had a valuable aid to diagnosis, and I have since then devoted a good deal of time to the subject. My methods of investigation at first were rather crude, but as years went on these improved, so that I was able to perceive that the matter was more complicated than it appeared at first. Thus there were different kinds of hyperalgesia. Two forms at least could be detected in the skin—*a* superficial and *b* deep. They were sometimes both present, and then the superficial lay within the wider-spaced deeper area. In many instances the areas were ill-defined, the borders being in a continual state of fluctuation—that is to say, one part when tested would be extremely sensitive, and a few minutes later it would be found no longer hyper-sensitive. This fluctuating region would be of a depth sometimes of 2 or 3 inches. Moreover, the size of the area was continually varying, and in some cases with the variation in the disease. Then other tissues besides the skin were found hyperaesthetic, such as the muscles and other subcutaneous tissues. Moreover, a sign often of greater help in diagnosis is the contraction of a few muscle fibres or of a portion of the abdominal muscle wall.

When Dr. Head put forth his views and described his "segmental" areas of cutaneous insensitivity, he was not aware of these varieties of cutaneous insensitivity, the reasons that has hindered the use of this examination is because no one could detect areas such as Dr. Head described. We now realize that cutaneous hyperalgesia does not appear in "segmental bands."

It is a curious matter that no neurologist seems to have sufficiently recognized the great importance of the peripheral distribution of the nervous system or of the skin as a sense organ. For instance, though Dr. Head reckons to tell us the parts of the brain which the pain stimulus reaches, neither he nor any other neurologist can tell us the mechanism by which the stimulus of pain or any other cutaneous sensation passes through the epidermis to reach the nerves which convey the sensation to the brain!

Dr. Head refers to some who "have tried to maintain that the viscera are 'insensitive' and incapable of generating afferent impulses of this order." As I have repeatedly stated that the viscera are insensitive, I take it I am included under the "some." But Dr. Head does not comprehend what is meant. I have found by an enormous number of observations that the viscera are insensitive to mechanical stimuli; that is to say, the stimuli which, when applied to the skin, produce pain, heat, cold, touch, when applied to the viscera do not produce these sensations. I have cut the bowel and stitched it, and pricked and pinched the various abdominal organs in conscious subjects, and no sensation has been experienced. Yet I am well aware that pain can arise from the viscera.

There are two points of great importance that arise from these observations which Dr. Head has missed:

1. The regions of the body which respond to mechanical stimuli such as those described above are supplied with cerebro-spinal sensory nerves. The regions of the body which do not respond are not supplied with these nerves but only with the sympathetic or autonomic nerves.

* This condition of fluctuation is turning out to be a matter of considerable importance in the functioning of peripheral nerves, for we have found it in constant operation in the normal process of life. We can trace evidences of its presence in the central nervous system, and even in the mechanism regulating the heart beat. It seems to be a part of the vital process concerned in the activity of all structures concerned in the production and conduction of stimuli.

2. Pain when it arises in the viscera is due, not to mechanical stimuli, but to a vital process.

If the first of these points is correct it opens up a new field in neurology. While my researches support this view, I recognise the matter requires further investigation, and at St. Andrews Institute the whole subject is being reviewed.

In regard to the second point, that visceral pain is produced only by a vital process, we are dealing with the most important part of the subject. Dr. Head speaks of tension as the cause of pain. Now tension, in the ordinary acceptance of the term, is not a vital process. You can distend a hollow muscular organ and make it as "tense" as you like, but you will not produce pain until you cause a contraction of the muscle fibres—that is, until you produce a vital process adequate to cause pain. The most effective stimulus for muscle contraction is stretching of the muscle fibres. A full uterus or bladder does not cause pain until the muscle contracts. Stone in the bladder does not cause pain until the contraction of the emptying bladder is stimulated to severe contraction by the presence of the stone.

Dr. Head says, "Tension is the most effective stimulus to any hollow organ; . . . but the injection of even a small quantity of fluid into the gall bladder 'so as materially to raise the pressure, will cause a profound disturbance due to the afferent impulses so generated.'" He has entirely missed the point in this experiment. You can give a distending enema and raise the pressure, but no pain is produced till the muscle of the bowel contracts. It is the contraction of the wall of the gall bladder, that is, the vital process, which produces pain—not the mechanical raising of the pressure.

The recognition of the fact that pain, the various kinds of hyperalgesia, and the contraction of the muscles of the external body wall are reflexes produced by definite stimuli, and the co-relation of these symptoms with the disease process holds out the prospect for one of the greatest advances in diagnosis that medicine has witnessed.

Recognizing this fact, we are given a clear line to follow, but it must always be remembered that such an investigation requires an accuracy of observation which is rare in clinical medicine. One of the greatest obstacles to the progress of clinical medicine is the absence of accurate observation, or rather the failure to recognize the need for accurate observation, as is shown by Dr. Head when he refers to precise descriptions of accurate observations as "hair-splitting dialectics."—I am, etc.,

J. MACKENZIE.

The St. Andrews Institute for Clinical Research,
St. Andrews, Fife, Jan. 12th.

TREATMENT OF CARCINOMA OF THE CERVIX.

SIR,—The object of my letter on this subject was to point out a serious error in Dr. Fletcher Shaw's paper and to suggest eclecticism in the operation, according to the situation and nature of the growth and the condition of the patient, as a possible means of improving the excellent final results given in Mr. Bonney's paper, which dealt with a series of 100 cases with a primary mortality of 20 per cent. I pointed out that this was about the same mortality as that of the chief foreign clinics—as given in Döderlein-Krönig's book on operative gynaecology, published last year (1921), the latest statistics available to me.

If Mr. Bonney has personally performed a second hundred operations and will give his results I shall be happy to quote them; but I do not think it is right to quote the results of the "last hundred" or the "last fifty" cases without knowing that the series was not selected, any more than it would be right to lower Dr. Shaw's 19 per cent. mortality by excluding his early cases, in which the mortality was higher.

Mr. Comyns Berkeley speaks of an absence of accuracy, responsibility, and courtesy in the critics of the results of Wertheim's operation. When a man without obvious cause uses intemperate language of this sort one naturally concludes that he has been touched on a sore spot. I wonder if Dr. McCann's and Dr. Shaw's allusion to the fallacy of the "operability rate" is responsible for this outburst. It is very difficult for an individual to give his "operability rate," though a hospital "operability rate" could be given. At the Middlesex Hospital it would include the cases in the special cancer wards. If the gynaecologists see cases in these wards, the cases should be included in determining the "operability rate."

But let us see what Mr. Berkeley's "operability rate" means. In 1916 (BRITISH MEDICAL JOURNAL) Berkeley and

Bonney stated that they had operated on 100 cases. For the first 70 they stated that their operability rate was 62.5 per cent. For the remaining 30, owing to the increased number of advanced cases seen, they would not give their operability rate, but did not hesitate to apply the operability rate of 62.5 per cent. to the whole series. And now Mr. Bonney applies this operability rate to a further series—it is true he gives it as 63.5 per cent., but this is evidently a misprint—and says, "the 100 cases with which this paper is concerned represent, therefore, a selection out of 160 cases presenting themselves for treatment." This "inaccuracy" of Berkeley and Bonney is responsible for misleading even a gynaecologist, Mr. Forsdike, who alludes to an important point in his letter—namely, the deaths and disabilities of patients "explored" with a view to performing the extended abdominal hysterectomy.—I am, etc.,

London, W., Jan. 22nd.

HERBERT R. SPENCER.

SIR,—Mr. Comyns Berkeley appears to revolve in a small circle, and when he comes to rest he may yet acquire that attitude of sweet reasonableness to enable him to comprehend the purport of my first letter.

He seems to forget that the extended abdominal operation for carcinoma of the cervix is practised by surgeons all over the world, and that the mortality of an operation which is accepted from time to time is not that of Smith and Jones working individually or conjointly, but the average mortality rate based on the mortality statistics of a large number of competent surgeons.

Wertheim in his 500 completed operations published more than ten years ago had 93 deaths (18.6 per cent.), which were distributed as follows:

In the first 100	30 deaths.
In the second 100	22 "
In the third 100	17 "
In the fourth 100	9 "
In the fifth 100	15 "
Total	93

Further, it will be seen that the mortality for the last 200 cases operated on more than ten years ago is 12 per cent., whereas Mr. Berkeley states "that the operative mortality for the last 200 operations conjointly performed by me and my colleague was 13.5 per cent." Although individual operators may from time to time be able to achieve a diminished mortality, which I have achieved in my own work, yet the mortality of the operation must be reckoned by the results obtained from a large number of competent operators, and for this reason I maintain that the mortality still remains at, roughly, 20 per cent.

This high rate can and will be reduced by better technique, and by the exercise of judgement in the selection of cases. As the extent of the disease can often only be determined by abdominal exploration, this should be done in all cases, which are otherwise suitable, and if the disease be found to be irremovable the operation should be abandoned and subsequent palliative treatment employed.

In conclusion, I would only remark that Mr. Berkeley's sense of humour is such that it causes him to laugh at the wrong time.—I am, etc.,

London, W., Jan. 22nd.

F. J. McCANN.

SUICIDE IN BORDERLAND CASES.

SIR,—With your permission I will briefly deal with a few only of the truly momentous questions arising from Dr. S. E. White's letter in the JOURNAL of January 14th (page 79).

First of all I express the following opinions: Melancholia is a functional disorder. Recovery from it takes place in course of time in practically all who are neither senile nor suffer from chronic disease. All at one stage or another of their illness are potential suicides.

Dr. White writes: "The success of treatment is to be measured by recoveries, not by a drastic system of repression." Those who commit suicide she must admit do not recover. What percentage of suicides does she consider legitimate and permissible under the system of care she advocates? And are the alternatives only her suicidal system and the so-called drastic system? Is there not a rational system? I will say nothing of the loss of valuable lives under the suicidal system, which she faces with brave unconcern, almost all of whom would have recovered under appropriate care, but I will add this from my own observation, that more than one of those who have been in some measure responsible

for such suicides have themselves afterwards broken down from distress resulting from the tragedy. I must apologize for calling her system "suicidal" for short, but no one will, I think, misunderstand what I mean.

Next, Dr. White has not grasped the essential difference between the natural depression, which is a reaction to an appropriate cause in the environment, let us call it melancholy, and melancholia, which is a morbid state, a disorder of the mind, which arises in the majority of cases from no known cause whatever, and the occurrence of which is a mystery even to the patient himself. As is well known, it is often rhythmical and periodic. It is true that in many cases some "slings and arrows" of ill-luck may have been the exciting cause of the attack, but true melancholia, once it has developed, continues independently of this cause, bears no relation either in intensity or duration to it, and it may be quite forgotten; further, the character of the depression is essentially different. It is, in Maudsley's words, a species of caricature of the natural phenomena.

Dr. White, having found that melancholia is natural melancholy, next proceeds to point out that in most cases suicide is no proof of mental aberration. By implication she appears to go much further. The worst cases, she says, may occur in persons with unclouded minds and with altruistic motives, and such acts of suicide may be regarded as heroic. The philosophy of suicide by sane persons is a very abstruse subject, but when we are dealing, not with the sane but with insane persons suffering from melancholia, our line of action, in my opinion, is a very direct and simple one—namely, to prevent it and earn the gratitude of the patient when he recovers.

Lastly, Dr. White wishes to do away with asylums, and to try the effect of hostels, apart from lunacy. There is nothing in the world to prevent the treating anywhere those who "do not need to be certified," but in the meantime what are we to do with those tens of thousands who do need certification? Asylums are necessary just as much as hospitals. Everyone will agree with her that hostels or homes are needed for the early treatment of mild and doubtfully uncertifiable cases of mental disorder. We are all everywhere doing what we can to obtain these. In Edinburgh over fifty beds are now available for this purpose, thanks to our system of lunacy laws; but unfortunately such treatment is open only to those who can afford to pay for it. But, whether treated in an asylum or a hostel or a home, the patient suffering from melancholia must be prevented from committing suicide, though, let us hope, not by the employment of methods that can be described as "drastic."—I am, etc.,

University of Edinburgh, Jan. 21st.

GEORGE M. ROBERTSON.

Sir,—My own experience in over a quarter of a century of practice, many years of which have been given to dealing with nervous and borderland cases, leads me to agree entirely with Dr. G. M. Robertson's dictum as to every melancholic being a potential suicide. If the physician who has charge of such cases takes any other view, he will some day get a very rude awakening. It is questionable if almost any system of guarding other than that used in the condemned cell will entirely preclude the risk of suicide, but the "open door" treatment of such cases would inevitably lead to frequent suicide were the treatment carried out in a sanatorium such as advocated by Dr. White. To entirely prevent suicide in such cases is almost impossible.

I have known of a patient choking herself with a bread poultice, and being found dead by her husband's side in the morning, black in the face! I once had to go and cut down a lady—in rooms—who had "swung off" from the curtain pole during a moment's absence of her nurse. I recall another man who drove a three-inch metal pocket-knife handle and blade into his head through his temple with a lump of coal, during a similar very brief unguarded moment. This was in a nursing home, and the remarkable thing was that the patient, owing to the downward course of the knife, did himself no vital injury and made a perfect recovery.

In July, 1920, a patient I had been treating at a hydro-pathic came to bid me good-bye, and stated he was now quite well and very grateful and so on. He had been very depressed and peculiar. A few minutes later he went for a motor run with his wife, who drove, beside her husband, the nurse behind. He asked her to stop a moment by a beautiful stretch of the Tweed (where the water was deep). A minute later he was drowning before his wife's eyes, deliberately gulping water down to choke himself. He left me at 11 a.m. and by half-past two I saw him stiff and stark dragged out

of the river. He had, we found, lost his watch and chain, pocket book, and loose silver, and everything of the slightest value, locked up in a drawer in the hotel. This indicated Scottish frugality perhaps, but more the deliberate and carefully concealed intention to do away with himself.

Such suicides can hardly be prevented in an institution even, certainly not in an open institution of the sanatorium type. The extreme resistive and almost certainly suicidal melancholic is best treated with all precautions in a proper institution—more so than almost any type of mental disease, because properly treated they almost invariably recover. Many such cases require forced feeding with mechanical restraint at the time.

Milder borderland cases where there may be no indication of but a possible suspicion of suicidal tendency can well be treated under private medical care without certificate, as advocated by Dr. G. M. Robertson in the *Times*, February 14th, 1920. Close association with a medical man whose sympathy the patient feels he has, will often be of the greatest help. The medical man, needless to say, requires to gain the patient's confidence and to acquire a certain personal dominance over him. This can hardly be gained over a large number of such patients. A few weeks ago an ex-soldier was admitted in a very unstable mental condition to a neurasthenic hospital in the vicinity of Bristol, with, of course, "the open door." About three days later he flung himself over the highest cliff in the Avon gorge and smashed himself almost to pieces. So much for cheerful sanatoria.—I am, etc.,

Clevedon, Somerset, Jan. 16th.

THOMAS D. LUKE, M.D.

Sir,—In the *JOURNAL* of January 14th Dr. S. E. White gives some views on suicide in borderland cases. In my opinion, if a case is committed to an asylum, that is, if the mental condition of the patient is such that it is necessary, under the present conditions in this country, to commit him to an asylum, then, if the case is one of a suicidal nature, to avoid such a calamity and get the patient well is surely the aim and object of an institution. Such an institution which boasts of never having had a suicide for over thirty years shows that it is run exceedingly well.

It would appear from Dr. White's remarks that no effort is made in asylums to cure a patient. It is regretted if cases are sent to an asylum that are unsuitable, but surely the asylum authorities would immediately deal with such a case after a short period of observation, and discharge him. Obviously the success of any treatment is measured by recovery, but in order to get such a case as is under discussion back to normal it is necessary for the patient to remain alive.

Surrounding us at the present time are many causes for natural depression, but should we begin to view these natural causes of depression in such a morbid manner that our minds refuse to function normally on other matters and we become obsessed with a hopeless future and feel that our nearest and dearest would be better without us, then surely we have reached the stage when we can be regarded as slightly mentally unbalanced and requiring treatment.

Dr. White mentions cases having attempted suicide being admitted to an asylum on account of depression due altogether to natural causes. It is agreed that the depression may be due to natural causes, but once an individual carries his depression to such an extent that he wishes to take his life, then he is not meeting the natural causes of depression with normal behaviour. It is obvious that it is not possible to change the conditions under which most of our patients are living, and therefore this explanation is not a solution of the problem. It is agreed that the dread of being taken to an asylum is a very great factor in precipitating a crisis in suicidal borderland cases, but in the absence of suitable institutions it is absolutely essential in many instances to have patients certified in order to preserve their lives for future activities, and I contend that it is better to tide a man over a temporary breakdown by certifying him and sending him to an asylum than to allow the grave risk of his destroying himself and so defeating recovery and removing from his wife and family the hope of future support.

Suicides are far more frequently the termination of a deranged mind than the reverse. One comes across the patient who has worked himself very, very hard, and at the age of 45 to 50 has a severe breakdown and becomes temporarily very suicidal. This type of case generally suffers from an enormous exaggeration of minor facts, and will regard the termination of his existence as being the very best solution for his nearest and dearest. There is not the slightest sanity about such a train of thought. His relatives all love

him, and he is probably the best of husbands, fathers, or brothers, and it is their dearest wish that his life should be preserved and that he should be guarded against committing any injury to himself. This is one of the commonest types that one meets, and I think a large number of suicides we see in the daily papers would come under this heading. The suicide's clarity of vision is only for himself, and all his arguments and statements are quite easily broken down but not eradicated, at any rate for some time.

Suicide is not so common amongst women as amongst men. I think statistics show about three men to one woman as being the average. The commonest form of suicide in the male appears to be hanging, whereas in the female drowning seems to be the favourite. The spring of the year, about May, is the period in which most suicides occur. This, no doubt, may have some connexion with sexual life increasing the mental depression.

In time we shall have proper institutions for the treatment of borderland cases; cases being admitted for a period in order that the physician may have a good opportunity of effecting a recovery before resorting to certification. It is hard to treat a man who imagines that he is a poached egg and wishes to sit down on a piece of toast and regards the physician who tries to dissuade him from such a belief as the fool of the party, side-by-side with a hard-worked depressed individual who has got a temporary mental breakdown and whose reasoning powers have not entirely left him and is willing to extend every possible help of which his tired mentality is capable towards assisting the physician in his recovery. Nevertheless, it is far better in every case not to take the risk of the patient losing his life, but to send him to an asylum under proper supervision, and in all probability as soon as he has recovered from his attack he will be the first to come and shake your hand and thank you for having acted so wisely.—I am, etc.,

Ministry of Pensions Neurological Hospital,
Oulton Hall, near Leeds, Jan. 17th.

P. G. PHILLIPS.

MENTAL HOSPITALS.

SIR,—The plan now being advocated by the Mental Hospitals Association—namely, to set apart seven or eight asylums for voluntary boarders only, as described in the pamphlet just issued—can but result in these particular institutions being stepping-stones to certification, more especially as the treatment will be similar to that given to lunatics.

This was the method adopted during the war as a response to the outcry that the soldiers should not be certified before being given every facility for getting well first. The arrangement did not prove satisfactory, as it has resulted in the number of soldiers certified going up 300 per cent. since 1919.

The atmosphere and traditions of an asylum cannot be wiped out by merely calling a patient a voluntary boarder and the group of buildings a mental hospital. The voluntary boarder will still be held in the meshes of the lunacy administration. Any desire to leave the institution is likely to be met with certification, which often occurs under present conditions. The word "voluntary" becomes meaningless. The medical superintendent can always take it upon himself to say that the patient is not fit to go out. We do not want to perpetuate the system that has worked so disastrously with the soldiers.

There are, according to the pamphlet, 18,000 vacant places in the asylums. How is this? Have they been vacated, as in war time, by overcrowding elsewhere; or by increase in the mortality rate—already far too high? The real, crying need is for hostels—free from all stigma, from all association with lunacy administration—where a large percentage of cures is aimed at, where every effort will be made to stay the patient from becoming a permanent charge on the country. This scheme will obviously lead to great saving of expense.

The pamphlet asks for legislation. None is necessary for hostels without detention. This was emphasized specially in the memorial presented to the health authorities in July, 1914.—I am, etc.,

OCTAVIA LEWIS.

London, W., Jan. 23rd.

BIOLOGICAL EFFECTS OF X RAYS.

SIR,—I have read Dr. Curtis Webb's notes of a visit to Erlangen with much interest. Under biological considerations he refers to a theory evolved by Dr. W. J. Farrow of Oxford to account for the observed effects of α and gamma radiations.

It has been shown by several observers that a cell whilst undergoing mitosis is especially vulnerable to these radia-

tions. Starting from this fact, he says: "the essence of reproductive power is in the chromatin, and hard rays poison chromatin, acting probably by a process of oxidation or reduction, so setting free a ferment or toxin." Having thus obtained a mythical toxin from the action of radiations on chromatin, he proceeds to elaborate the theory by further assumptions in respect of antitoxins. Further, he says that "this hypothesis of a toxin explains the latent period before the effects of α rays manifest themselves." How it explains this is not told.

Everyone appreciates the value of a theory which truly leads the investigator, and also the danger of one which gives a false lead because it does not correlate the observed facts and thus has a false basis. I write to call attention to this danger.

Many attempts have been made to detect chemical changes in irradiated tissues and in the various substances of which they are composed; in the vast majority of cases no chemical change has been detected or only insignificant alterations. In contrast to these negative results, the evidence of physical changes is abundant; I refer more especially to alterations in colloidal state. The importance of colloidal states in the manifestations of living matter is every day becoming more clear.

When, further, we take into account, apart from biology, the numerous and profound physical changes which are known to follow exposure to α rays, and the difficulty of effecting chemical changes, must we not hesitate to accept a chemical theory as a working basis, more especially if physical explanations can account for the facts? For there is evidence that some of the biological effects are physical in nature—I refer to alterations in the permeability of membranes, and to the precipitation of colloidal solutions and suspensions, and perhaps to the mitotic changes. Lastly, it may be pointed out that α rays are effective in producing biological change only through the secondary cathode rays (negative corpuscles) which are produced on absorption. There is no doubt that chemical changes will occur later—for instance, after the death of the radiated cells, and it is just here that the latent period may be explained as an interval of time following physical changes before chemical changes supervene.

For these reasons I favour a physical explanation rather than a chemical, in which effects are thought of in terms of toxins and antitoxins.—I am, etc.,

MEDICAL ASPECTS OF DELINQUENCY.

SIR,—Dr. Tyson's letter of December 31st, 1921, p. 1130, is so immediately interesting to the profession that I fully expected a number of replies to it.

I quite agree with Dr. Tyson that the profession should have more representation on the magisterial benches, for these reasons:

- (a) Medical men have had a far wider education than have the majority of recently appointed justices.
- (b) Medical men have had some training in jurisprudence.
- (c) Medical men have had daily, almost hourly, to weigh the value of statements and symptoms of those they treat, or, in other words, to deal with evidence, and that is what the justice should do.

I do not agree with the necessity or value of a psychological expert. Personally I should have more confidence in the opinion, as a justice, of a medical practitioner of say some ten years' standing, because such men are daily in contact with the general public, the majority of whom are normal, whilst the psychological expert usually deals with cases of mental deficiency which are more or less pronounced; the opinions of such experts should have more effect when giving evidence, when they could be cross-examined and their evidence weighed with that of the other witnesses, than when their views are stated to their colleagues on the Bench. Unfortunately expert medical evidence, even in important cases, is generally so contradictory that neither jury, judge, nor the public are satisfied.

Neither do I accept the statement that it is the duty of the Bench to prevent crime. Their duty, which they have taken on oath, is to decide upon the weight of evidence whether the accused is guilty or not guilty. What the action of the Bench may be if they find the accused guilty depends upon many circumstances.

If any member of a Bench of justices has any doubt as to

the mental condition of a defendant he can ask for medical evidence. I have been a justice for over forty years, and sat on various benches in two counties and now at this borough, and I have never had any difficulty in obtaining medical testimony, either before or subsequent to the Mental Deficiency Act of 1913.

Even in cases where there have been convictions I have followed them up and asked for careful medical observation while under sentence. As a visiting justice for fourteen years to a large prison I have witnessed how well similar requests for observation are carried out.

At our recent borough quarter sessions, at which Dr. Tyson was present, I felt doubtful as to a prisoner's mental state, and so communicated with the Recorder, who evidently had similar ideas, for though the lad had had several previous convictions and had served a period in a reformatory, he simply bound him over and placed him under the observation officer. Here I would suggest that upon a second conviction the observation period should not be less than two years, with a careful medical examination.

For some years I have followed "observation cases," and am satisfied that the majority of those who relapse do so between the tenth and sixteenth months after their first conviction. Probably many even psychological experts will differ from my views; the chief object of this letter is to elicit such differences.—I am, etc.,

Folkestone, Jan. 13th.

P. BROONE GILES.

ENCEPHALITIS LETHARGICA AND MENTAL DEFICIENCY.

SIR,—In the BRITISH MEDICAL JOURNAL of January 21st, p. 122, Dr. Drummond draws attention to a statement of mine concerning the difficulty of dealing with children who show moral changes after recovery from an attack of encephalitis lethargica. In the paper in question (*Journal of Mental Science*, October, 1921) these character changes were mentioned as a problem for investigation rather than as an *ex cathedra* pronouncement upon procedure.

However, I hardly consider that Dr. Drummond proves his case, for he explicitly states that "no doubt these cases are not just the class for which the (Mental Deficiency) Act was intended." That was, and still is, my contention. The question at issue is not whether these cases are suitable for institution treatment, but how far they can be brought within the interpretation of mental deficiency as defined by the Mental Deficiency Act, 1913. There are, of course, cases in which the behaviour and the intellectual capacities have undergone so profound a change that they "require care, supervision, and control for their own protection, or for the protection of others," but there are not a few cases in which the alteration in character shows itself as an impish perverseness and lack of emotional control, evidenced, for example, in paroxysmal outbursts of temper, without very marked reduction in educational capacities. Similar results are common in adults, and relatives will, often reluctantly, admit on tactful inquiry that since the illness the patient has become "difficult" or "impossible." I do not think that anyone would suggest that such persons could be dealt with under the Mental Deficiency or Lunacy Acts. Yet these persons belong to the same category as children who have been similarly affected. The difference is one of behaviour—that is, of reaction to the environment of child and adult.

Dr. Drummond states that the two cases under his care were certified as "moral imbeciles on account of vicious propensities apparently resulting from their illness." I submit that to include such cases within the definition of moral imbeciles in the Act is to strain the interpretation which that definition is intended to convey. This view he himself appears to admit, for he writes that it would have been better to certify them as feeble-minded rather than as moral imbeciles. My own view is that while from a practical point of view the use of the term "moral imbecile" has advantages as a generalized description of a particular class of mental defectives, yet from a psychological standpoint it is misleading, for it appears to lend support to the supposition that there exists a specific ethical or moral sense, separate and distinct from the general capacity for reason and the formation of judgements.

The more we learn of the repressions of childhood and of the complexes which may result, the more clearly we shall become of diagnosing aberrant conduct as "moral imbecility." I need hardly say that I am fully in agreement with Dr. Drummond in believing that institution treatment is almost

always in the interests of these children, as it certainly is in the interest of psychological investigation. The comparatively simple environment of an institution may very possibly restore their emotional balance, so that they may, in course of time, reacquire that control of action which is a necessary qualification for civic life.

Dr. Drummond admits that this question of permanent incapacity is a stumbling-block round which a way has to be found if such children are to be dealt with as feeble-minded persons under the Mental Deficiency Act.

If the parents are anxious that their child shall be admitted to an institution, or at any rate are consenting parties to the petition, the case might be dealt with under Section 2 (a) of the Act, provided that the Board of Control was prepared to accept the medical certificates as describing a person who may properly be dealt with under the Act. The difficulty will arise if the parents withhold consent, for many magistrates will not be prepared to make an order if they are not satisfied that clear evidence as to "an early age," "permanent incapacity," etc., is forthcoming.

The whole subject is full of administrative and psychological interest, which must be my excuse for the length of this letter.—I am, etc.,

Birmingham, Jan. 22nd.

G. A. AUDEN.

SPINAL ANALGESIA.

SIR,—In his interesting paper on "Eleven thousand cases of spinal analgesia," published in the JOURNAL of November 5th, 1921, Mr. Morrison has not mentioned the actual composition of the solution of stovaine which he uses. I think that possibly the explanation of the persistent headache as an after-effect may be found to lie in the composition of the solution, and perhaps also in the large amount which he injects. Possibly it lies partly in the amount of strychnine injected. What is the strength of the solution? I think he might find headache less frequent and persistent if he were to employ a preliminary injection of morphine and scopolamine.

There is one disadvantage of spinal analgesia—a very real one—which he has not mentioned, and that is the dread of many patients of being pierced in the spine with a needle. Will he tell us how he gets over this? I freeze the skin with ethyl chloride spray, then nick the skin with a scalpel before inserting the needle.

It would be interesting to know how Mr. Morrison ensures anaesthesia for operations on the upper part of the thorax and on the clavicle. Perhaps the specific gravity of his stovaine solution would give the answer. Will he kindly state what that is? Undoubtedly the abdominal relaxation obtained under stovaine spinal analgesia is very complete and satisfactory, and it is a marvel to me that this method has not more completely displaced general anaesthesia for abdominal work.

In the same issue of your paper Dr. Stuart Stock discusses Mr. Boyle's article on "Anaesthesia" published in the JOURNAL dated October 15th, 1921. Referring to ethanesal as a non-toxic inhalation anaesthetic, Dr. Stock adds that "future progress lies along this line of research rather than in the devising of new ways and apparatus to give the older drugs." May I suggest that perhaps future progress also lies along the line of local and spinal analgesics which at one stroke abolish nearly all the dangers and disadvantages of general anaesthetics, whether new or old. I think the day may come when the giving of a general anaesthetic, except in rare and selected instances, for an abdominal operation will be regarded, in Dr. Stock's words (referring to something else), as "little short of a surgical catastrophe" which "must have weighed heavily in the balance against them" (the patients).—I am, etc.,

Indore, Central India, Dec. 2nd, 1921.

W. R. BATTIE.

MEDICINE IN ASSAM.

SIR,—I was much interested to read the article on medical work in Assam, in the JOURNAL for December 31st, 1921, page 1128.

I was never a tea-garden doctor, but I was for some years district medical officer on the Assam-Bengal Railway, stationed in Assam, and I was the first secretary of the Assam Branch of the British Medical Association. Consequently I knew personally most of the men practising in the province, and had many opportunities of seeing the conditions of their work. I can unhesitatingly support every-

thing that my old friend Dr. McCombie states in his reply to Dr. Fordo.

A keener and more efficient body of men than the majority of the tea-garden doctors it would be difficult to find, and many of them have done good original work in tropical medicine. In their relations with the garden managers everything depended on the possession of their confidence, and once a medical officer had proved himself, his recommendations were always listened to and carried out as far as possible. Of course, nobody ever got all he wanted—what sanitarian ever does? But tea-garden managers are intelligent, educated men, and for the most part thoroughly realize that money spent on sanitation pays good dividends in the increased efficiency of the labour force under their control. As Dr. McCombie says, there is not much opportunity for surgery, but in parasitology and tropical medicine generally there is an unequalled field.

If Dr. Fordo had stuck it out and proved his worth, he would have had a very different tale to unfold.—I am, etc.,

W. A. MURRAY,

Late Medical Officer, Assam-Bengal
Railway.

Harrogate, Jan. 3rd.

SIR,—Dr. Fordo's description of the medical arrangements on the tea gardens of Assam is accurate. The great drawback to the life of the "planters' surgeon" is, in my opinion, the general conditions under which he has to live. The doctor, in the words of one of the senior managers, "is fair game for everybody," his means of getting about are almost impossible; I, for instance, was expected to travel over twenty miles at least once a week on a horse that could hardly carry itself. It is true that the so-called "medical committee" of managers had arranged that I should find my own means of transport, but they did not tell me anything of the difficulties of travel, etc., before I went there. My advice to those whose sentimental ideas of romance and adventure in the East overcome their better judgement is not to take one of the tea-garden appointments—

1. If you are married.
2. If you are offered anything less than Rs.800 a month, together with a free, furnished bungalow to yourself.
3. Unless your first-class passage is paid to and from the place.
4. Unless the usual three years' agreement contains a clause to the effect that you can relinquish the appointment at any time on giving three months' notice in writing.
5. Unless the position as regards the means of getting about is explained. (This is important.)
6. Unless medicine occupies a secondary place in your preferences.

By all means take one of these appointments if—

1. You like games and riding (and polo).
2. If the tropics appeal to you.
3. If you do not feel particularly concerned as to the matter of "saving for a rainy day."
4. If you are lucky enough to get one of the really good billets; there are just a few.
5. If surgery does not appeal to you.
6. If you are in the pink of health and can stand anything.

—I am, etc.,

January 3rd.

EXPERIENCED.

HOSPITALS IN THE TERRITORIAL FORCE.

SIR,—Dr. Bertram Rogers writes rather in anger in reply to my letter on the future of the Territorial general hospitals. It is an unfortunate attitude from which to approach this question, for it has led him to make a communication built up mainly on the two logical fallacies known as *ignoratio elenchi* and *petitio principii*. In plain words, he begs the question and misses the point.

The question that he begs is whether it is better that these great institutions for the treatment of the sick and wounded soldier—and that is their only *raison d'être*—should be run on the rigid military lines which were followed during the war, or whether they should be constituted on the model of the great civil hospitals which has been evolved from the experience of centuries. Dr. Rogers settles this by his statement:

"The system is the best yet devised for soldiers and the well-being of the patients; the efficiency of the administration and the comfort of the officers depends entirely on the qualities of the officer commanding and on him alone."

No doubt that is so under the system in force during the war; but the statement carries with it its own condemnation. To make the efficiency of a hospital to depend on the qualities of one man whose only qualifications might be that he held a

commission of lieutenant-colonel, and that he had acquired his experience by having done "a year's training in a military hospital," was surely a gamble equal to the gamble of the Dardanelles campaign. The "military hospital," it must be remembered, was a regular military hospital where he could certainly learn the whole system of army forms, and incidents and official correspondence and all the rest of the red tape of the army, but where he could never acquire the art of working with the medical officers he would meet in the Territorial General Hospitals, officers designated in the "Regulations of the Territorial Force" as "distinguished members of the medical profession," and intended to be treated as such. Nor did his original appointment as administrator ensure anything—it was the "accident of any accident"—he might be a distinguished hospital surgeon or physician, or a general practitioner with no experience of hospitals except as a student, or a professor of anatomy or of any other science. And yet on him depended "the efficiency of the administration and the comfort of the officers."

That is the military system, highly essential in the organization of a battalion fighting in the field, but of very doubtful value in the conduct of a great hospital for the treatment of injury and disease. The "benevolent despot" would no doubt always make the best governor if only he were competent as well; but so far the world has failed to find him; and that is why a good system of government is so very important. Of course no system can ensure efficiency if you get the wrong man to work it, but human nature being what it is the better the system the better the result.

Now the system which seems to me to be the best is that by which our great civil hospitals are run. Dr. Rogers says there were "no gaps" in the Territorial hospitals. I have mentioned two—namely, the absence of medical boards and the want of resident house-surgeons. Dr. Rogers is pleased to jest as to medical boards, and to imply that, once you do away with the unchecked autocracy of the C.O., you are reduced to a sort of Soviet government of medical officers, nurses, orderlies, and patients. The importance of a medical board in a large civil hospital is well known to those who have sat on one, and its suggestions are almost invariably adopted by the lay committee who find the money and manage the business affairs of the institution. Why is it out of place in a hospital where the patients happen to be men in uniform instead of out of it?

The want of house-surgeons was obvious, and should have been met from the earliest period of the war.

Dr. Rogers's treatment of my complaint that consultants were set to do the mechanical work of signing letters and forms and railway warrants and the like is an example of his missing the point. His answer is:

"For my own part I cannot see why the clerical work of making formal replies and filling up forms cannot be done by the sergeant-major or even less highly placed N.C.O. Does the 'Late Captain' wish to do it himself?"

My complaint was not that the N.C.O. wrote the letters but that a busy consultant should have had to waste hours in the mechanical work of signing them. But that is the army system which is "the best yet devised." Not even a rubber stamp was permitted. In my civil capacity I happen to be a magistrate, and I often sign warrants committing a man to prison by a rubber stamp. But to thus complete some form "passed to you, please," is "flat blasphemy" in the army. The main point is, of course, the waste of valuable time involved.

Dr. Rogers is good enough to say that I have never learnt the "first duty of a soldier—namely, to obey." Again I say that I agree that that is the first and most imperative duty of the soldier. But we *à la suite* officers of home general hospitals were in reality nothing but civilians in uniform. Our responsibilities were to the sick and wounded; we were not ordered to apply such-and-such treatment to our patients; our duty was to use our knowledge and our judgement to do our best for them. The soldier is ordered, and rightly ordered, by his superior to do exactly what his superiors think right. If I had been ordered by my commanding officer to amputate the leg of a soldier when I did not consider it necessary to do so, I should have refused, and no court-martial would have ordered me punishment for refusing. But if I had been the captain of a company in the field ordered to attack a certain position and had refused, I should have been shot, and deservedly so. Here is an illustration of the folly of applying military methods to matters which are not really military at all.

Of course there is a class of mind to which all the pomp of

military methods appeals with great force. They love the titles and the rank, the constant salutes, the standing to attention (or at ease) of patients when the medical officer goes round the wards, and the rest of the parade of the army. Very necessary, I again agree, for armies in the field. But is all this necessary for the welfare of hospitals at home? On the contrary, does it not tend to throw into the background the real object for which these hospitals exist? After all, the real problem is this—namely, how best to employ all the best medical and surgical talent of the country for the benefit of the soldier in time of war. My own opinion is that it is unwise to attempt to apply the methods of the regular army to any future Territorial General Hospitals. Dr. Rogers thinks otherwise; but he would be doing a real service if he would explain why, as he says:

"The *à la suite* hospitals have not come up to the expectations that were formed of them and a new system is necessary. I need not say how or why they failed. Anyone who was in charge of a hospital during the war, and kept his ears and eyes open, knows why."

That is not very illuminating. If he knows why he should surely tell us.—I am, etc.,

January 8th.

LATE CAPTAIN R.A.M.C. *à la suite*.

VIENNA AND LONDON.

SIR,—I have obtained and have studied a copy of the programme of the post-graduate courses now in progress in Vienna. It is a broadsheet printed on both sides. On the one side are the particulars of a course designed apparently for general practitioners and consisting of a score or more lectures and demonstrations, by as many authorities, on diseases of the digestive organs and their treatment. The course lasts the inside of a fortnight, and the charge even to an outlander is only 10,000 kronen, or something less (so I am told) than 10s. at the present rate of exchange in Vienna. On the other side is announced a long series of courses on a great variety of subjects, from ordinary anatomy to the use of those latest instruments of clinical precision—the bronchoscope and the ureteroscope; the charges for most of these courses vary from 5,000 kronen to 200,000 (£10), but in respect of some it is stated that the post-graduate must make his own terms with the teacher, and I have heard rumours of as much as £100 being charged; but this may be for a course in English, and it may be, too, that the total is divided among all the attendants: if they numbered ten, or even five, the charge to each might not be out of the way.

Incidentally, I would ask the Executive Committee of the Fellowship of Medicine and Post-Graduate Association whether it might not follow the example of Vienna and replace its extravagant weekly bulletin by a broadsheet such as this, which contains all the information for a whole quarter any possible applicant can want.

But it is not on this very minor point that I am moved to write. I see that the broadsheet is issued by the Wiener Medizinische Fakultät: the courses, then, are organized by the medical faculty of the University of Vienna. I seek information as to what the University of London and its medical faculty have done to help in the organization of post-graduate teaching in London. I pause for a reply, suggesting only that the properest person to make it is the Dean of the Faculty of Medicine, who is also, I believe, the representative of the Senate of the University on the Council of the Fellowship of Medicine and Post-Graduate Association.—I am, etc.,

January 21st.

PALINURUS.

THE INHERITANCE OF ACQUIRED CHARACTERS AND OF MATERNAL IMPRESSIONS.

SIR,—There has been for a long time, and there still is, a diversity of opinion amongst biologists as to the inheritance of acquired characters. Some affirm that such inheritance does take place, at any rate occasionally; others affirm that these characters are never inherited, and they proceed to explain how such an occurrence is impossible, because, for a character to be inherited, the factor upon which it depends must exist in the germ plasma, by means of which it is conveyed from parent to offspring; whereas an acquired character, not being of germinal origin, is not inherited, nor, indeed, can be. A feature which is not characteristic of the species, and which makes its first appearance after birth, or, indeed, at any time after conception, is an acquired character, and is not transmitted from parent to offspring.

A familiar example of an acquired character is the "docked" tail of a fox terrier. The docking takes place after birth, and is an artificial modification; it does not depend upon the germinal constitution of either parent, and is never transmitted, so far as I have been informed. On the other hand, the features which are specially characteristic of the fox terrier breed, such as size, general build, shape of head, colour, texture of coat, and "mental" qualities, are dependent upon the germinal constitution derived from the parents, and are inherited.

A conflict of opinion also exists in regard to the influence of maternal impression. Some observers contend that strong, violent, or unusual impressions, whether mental or physical, experienced by the mother during pregnancy may, and sometimes do, produce an associated modification in the offspring, and there undoubtedly is a strong and widespread tendency to attribute any abnormality in the child to some unusual effect experienced by the mother during pregnancy. Others declare that such a sequence or apparent correlation is merely a chance coincidence.

There are great difficulties in testing these questions in the human subject by the experimental method, so that we are practically restricted to observation. As a matter of fact, however, the late war has supplied us with the conditions of experiment on the grandest scale, and it is very desirable that full advantage should be taken of the opportunity. Many mothers must have experienced unusual and painful impressions during their recent pregnancies, and thousands of men who fought, and were more or less mutilated by gunshot or otherwise, have become fathers since returning home.

If acquired characters are inherited to any marked extent, or if there is solid ground for the prevalent belief in the influence of maternal impressions, surely we ought to meet with some instances in the families of our ex-service men. If any such instances are observed they should be reported, and I would like to suggest that such reports should not be published in various journals but sent to some central office, where they can be collected and investigated. Probably the best place is the Eugenics Laboratory of University College, London. This is under the direction of Professor Karl Pearson, who, I am sure, would be glad to receive and deal with any reports sent to him.—I am, etc.,

Wrexham, Jan. 19th.

H. DRINKWATER, M.D.

TREATMENT OF GONORRHOEA BY ELECTROLYSIS.

SIR,—My paper in the BRITISH MEDICAL JOURNAL of December 31st, 1921, reported the results obtained in 500 cases. This led to a letter from Mr. Wyndham Powell, in which incredulity was expressed at more than one aspect of the work, though at the outset he declined to enter into the value of the method. This latter is all that matters to the profession or the public. His latest letter is directed entirely to personal opinions on irrigation, which is not the principal matter.

In view of the need for improvement in the treatment of gonorrhoea the experiences of others of the positive value of electrolysis would, I believe, interest your readers.—I am, etc.,

London, W., Jan. 22nd.

CHARLES RUSS, M.B., M.R.C.S.

SIR,—I was pleased to see that Mr. Russ was able to publish a further series of cases of gonorrhoea treated satisfactorily by electrolysis.

Whatever may be the facts and their interpretation concerning the pathological lesions of an infected urethra there can be no doubt that many patients up and down the country have reason to be grateful to Mr. Russ for his investigations. I hesitate to accept all Mr. Wyndham Powell's findings as correct, as they are in many respects contrary to my own experience; especially is his statement that a second infection can be cured in a week or ten days open to discussion. It must, however, be admitted that many years will elapse before a final verdict, as to whether strictures do or do not occur under electrolytic treatment, can be finally given. That they do form when irrigations are largely used we know full well, and we seldom meet a patient with a stricture who does not give a previous history of a long course of lavage at some earlier period of his life.

In 1917, as a temporary surgeon lieutenant in the navy, I found myself in Italy with spare time and a large number of cases of gonorrhoea. Having read Mr. Russ's book I had the necessary rheostats and apparatus made on board, and,

following his methods closely, proceeded to treat the cases. Those with fresh infections were chosen, and in all a cure was obtained more rapidly than by any of the orthodox methods. Treatment was given daily or on alternate days, and after about the tenth application the patient's urethra was "dry," that is to say, no sign of discharge could be found macroscopically—a condition rarely seen so soon under other methods. Further applications were given at wider intervals until no threads were voided in the morning specimen, this being the rough and ready but practical standard of cure used in His Majesty's ships.

A microscopic examination of the urine of several patients was made later in the Army Hospital at Gibraltar, and in nearly all of these no gonococci were found. It must be remembered, too, that the whole treatment was carried out in an experimental manner with home-made apparatus in a foreign country, away from many of the ordinary facilities of practice. Subsequent elaboration of the technique has only further convinced me that we have in this method a valuable new weapon. Admittedly it has its limitations, the chief being that as each case must be treated individually for some time every day it is more suitable for private practice than for dealing with large bodies of service patients. This, however, should not deter us from practising it whenever opportunities offer.—I am, etc.,

Westminster, S.W., Jan. 7th.

G. MURRAY HEIRON.

SIR,—Anyone taking the trouble to look over the monographs and subject matter of the principles of Dr. Charles Russ's work on the treatment of gonorrhoea, cystitis, ulcers, septic hands, etc., will see that since 1910 there has been a continuous development of that work. Moreover, anyone who has had the opportunity of seeing (as I have) the results of his treatment, especially in gonorrhoea, can but recognize the powerful weapon Dr. Russ has placed in our hands for the treatment of many septic processes.

In consequence of the widespread adoption of his electrolysis treatment by medical men, both in their private and institutional work, it appears now to be the time to ungrudgingly admit its value and acknowledge the good results we can attain through it.—I am, etc.,

VIVIAN WALL, L.R.C.P., M.R.C.S., L.S.A.,
Late R.M.O., London Lock Hospital (Female).

London, W., Jan. 27th.

PELIOSIS RHEUMATICA.

SIR,—I read with much interest Mr. H. V. Jackson's letter in your issue of December 24th, 1921, on "A case of peliosis rheumatica." The disease is no great rarity in Constantinople. My experience of it, however, leads me to differ from your correspondent as regards the first of the three points he mentions as distinguishing this affection from acute rheumatism. I recall one case at least (ending in death) in which the joint pains were excessively severe, so severe, indeed, that the mere movements of persons in the sick-room seemed to cause the patient exquisite suffering. (Osler, too, I may recall, states that "the joint affections are usually slight, though associated with much pain.")

In another case a complication developed which I have not found mentioned in any textbook. The case was a mild one, and all the symptoms were subsiding when pain and redness appeared in one eye, rapidly proceeding to an acute panophthalmitis and destruction of the organ. The rapidity of the process was remarkable. When seen one day at 2 p.m. there was no sign of eye trouble; but on the next day's visit at 6 p.m. there were intense chemosis, violent conjunctivitis, irido-cyclitis, pus in the anterior chamber, and the eye was already doomed. Unfortunately neither the patient nor his friends had realized the gravity of the condition; they sent for me during the twenty-six or twenty-seven hours that had elapsed since the eye symptoms set in, and the eye had consequently remained without treatment during that period.

The complication made no difference to the course of the general disease, which steadily and indeed rapidly subsided.—I am, etc.,

Constantinople, Jan. 12th.

F. G. CLEMON, M.D. Edin.

MULTIPLE TOOTH EXTRACTION.

SIR,—There is no doubt that a considerable number of teeth are extracted for diseases to which they have no relation, and there is also no doubt that in some cases many teeth are retained which might have been sacrificed to the benefit of the

patient. The difficulty is to determine the degree of infection for which they may be responsible. Mr. Denison Pedl assumes that by clinical examination he was able to determine that a patient of his, a doctor, had two teeth which were the cause of his ill health. The teeth being unserviceable he extracted, and the others, which he is treating, he retaining, to the advantage of the patient.

Now, the misfortune about pyorrhoea alveolaris is that it is impossible clinically to determine the degree of infection of the alveolar process, and many cases submitted to radiological examination are found to show deep infection of the bone-show, in fact, a chronic alveolitis.

The all-important question is, Can this osteitis be cured by local measures when the teeth are retained? My impression is that it cannot be cured, so that even if the gum margins by treatment be given a healthy appearance the patient is still suffering from osteitis and getting infection by way of the lymphatics.

In cases of oral sepsis supposed to be related to systemic disease it is doubtful, except when the local disease is advanced, whether the clinician can give a sound opinion without a careful examination of radiograms of the jaws of his patient.—I am, etc.,

London, W., Jan. 16th.

STANLEY COLLYER, M.D.

THE VALUE OF FRUIT JUICE.

SIR,—Dr. H. C. Cameron, whilst rightly castigating the exploitation of the word "vitamin," fails to appreciate the importance of fruit juice in therapeutics when he says, "Fruit juice will not do anybody any harm. It will cure and it will prevent one thing only—scurvy."

If he will recall the experience of the ages as to the value of grapes and oranges in all febrile conditions, and of the important effects of apple pulp and apple juice in chronic nephritis, and will, for example, experiment with and observe the result of the use of raisin tea in gastric catarrh, and the debilities connected with atonic indigestion, he will, I think, place on a far higher standard various fruit juices in the prevention and treatment of ailments which are greatly reducing the happiness of living.—I am, etc.,

London, W., Jan. 16th.

JOSIAH OLDFIELD.

ROYAL MEDICAL BENEVOLENT FUND.

At the meeting of the Committee held on January 10th 18 cases were considered and £181 voted to 14 applicants. The following is a summary of some of the cases relieved:

Daughter, aged 66, of M.R.C.S. Eng. who died in 1895. Owing to diminishing income applicant finds it difficult to pay her way. She received last year £28 for copying work, £30 from dividends, and a Christmas gift of £5. Rent, light, and use of kitchen stove cost 14s. per week. Voted £18 in twelve instalments.

Widow, aged 62, of L.R.C.P. Edin. who died in 1909. Applicant receives boarders and is helped by a niece. She asks for help towards paying mortgage interest. Relieved eleven times, £110; last time £10, January, 1921. Voted £10.

Daughter, aged 69, of M.D. Edin. who died in 1875. Applicant and her sisters are unable to meet their expenses; their income amounts to £127; rent and rates £50 per annum. Relieved six times, £78; last £18, January, 1921. Voted £18 jointly.

Widow, aged 80, of M.R.C.S. Eng. who died in 1870. Applicant's income is diminishing and last year she only received £12 from a married daughter. Ground rent and her board and lodging cost £12 per annum. Last £12 in twelve instalments, December, 1920. Voted £12 in twelve instalments.

Daughter, aged 48, of M.R.C.S. Eng. who died in 1885. Through ill health she is entirely dependent upon her sister. Relieved by the Fund five times. Last time, £10, April, 1920. Voted £10.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters J. Symonds, K.B.E., C.B., F.R.C.S., at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild is overwhelmed in these days of exorbitant prices for clothing and household necessities, with applications for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for secondhand clothes and household articles for the benefit of the widows and children who in happier times would not have needed assistance. The gifts should be sent to the Secretary of the Guild, 43, Bolsover Street, W.1.

ADMISSIONS to the clinic of the Innsbruck medical faculty have been suspended, as the number of medical men in the country is considered to be excessive. Owing to financial strain the administration of the principal hospital in Innsbruck has limited the number of beds to 300, and has dismissed a certain number of its medical and nursing staff.

Obituary.

EDWIN RAYNER, M.D., F.R.C.S.,

Formerly Treasurer of the British Medical Association.

MEMBERS of the British Medical Association will learn with regret that Dr. Rayner, Treasurer of the Association from 1907 to 1916, died on January 18th. He had been in failing health for some years, and last autumn underwent the operation of prostatectomy. He had attained the age of 77.

Edwin Rayner was a member of a family long settled in Stockport. He was the eldest son of Dr. William Rayner, who was a member of the Stockport Town Council for twenty-three years and mayor in 1883-4. His son received his early education at the Stockport Grammar School, of whose governors in later life he was chairman. His scientific education began at Owens College, Manchester, and was continued at University College, London, and in Paris. He graduated B.A. London in 1863, but his time in Paris was something more than a passing visit, for he took there the degrees of B.L. and B.Sc. in 1864. He always retained a strong interest in French medicine, in which he was well read, and also in French politics; the capacious pockets of the rather old-fashioned coat he affected were seldom without one or two copies of the Paris newspaper to which at the time he happened to be subscribing. He was British juror in the class of medicine and surgery at the International Exhibitions held at Brussels in 1910 and at Paris in 1911.

As a young man he held the appointments of house-surgeon and house-physician at University College Hospital. He graduated M.B. London in 1869, taking honours and the gold medal in forensic medicine, a success which put him in a position to graduate M.D. in the following year. He was an Associate of Owens College, Manchester, and in 1883 received the degree of B.Sc. from the Victoria University. He had taken the diploma of F.R.C.S. Eng. in 1859. He settled in Stockport, and for many years his activities were closely associated with that rapidly growing town which, though in the county of Chester, is only five or six miles from Manchester, and, like its big neighbour, is a busy centre of the cotton trade. He was for nineteen years medical officer of health and public analyst for the borough, offices he resigned in 1892. He was a hard working member of the staff of the Stockport Infirmary, and after serving for thirty-four years as surgeon was in 1903 elected consulting surgeon. He was J.P. for the borough and took an active interest in its affairs, showing himself always ready to promote medical and social schemes for solving the many difficulties which inevitably arise when the growth of trade causes great increase of population on a cramped site. He was an original governor of the Pendlebury Orphanage, and was eventually chairman of the governors, and had been a magistrate for the borough of Stockport since 1880. During the war he interested himself in the establishment of an auxiliary military hospital in Stockport, and was an active member of its surgical staff.

Dr. Rayner had long been a member of the Association when in 1894 he was elected President of the Lancashire and Cheshire Branch. Then as now, perhaps then even more than now, that large and active Branch exercised a great influence on the policy of the Association, and Rayner's interest in its administration may be said to have dated from his tenure of this office. He represented the Branch on the Council in 1896-97-98, in 1903 and 1904, and again in 1905 and 1906. As he became a member of the Association in 1877 he had known it before the reconstitution of 1883, the principles of which he never approved. The old plan of a large Council, meeting once a year, with a committee of council elected out of it to maintain continuity in the administration of the affairs of the Association, had many defects and was not wholly logical, but it at least put the final decision into the hands of a body of men who were constantly interested throughout the year in the work of the Branches. The constitution of 1883 reduced the size of the Council and made it the actual administrative body, meeting quarterly and holding also several meetings during the annual meeting. The Association, however, remained a company (trading not for profit) and the Council was required to make an annual report to the general meeting of the company. The vast majority of members took very little interest in this meeting, which was more or less a chance assembly of those attracted by other considerations to the town in which the annual meeting was being held. A certain number of members

critical of the proceedings of the Council, however, made it a practice to attend, and discussions ensued which were often acrimonious and seldom edifying. The need for a reform in procedure had become evident.

Rayner was an old-fashioned English Liberal in politics and a firm believer in the representative system of government as commonly understood. He therefore welcomed proposals for a revision of the constitution, but the idea of delegation with which many of the most active reformers were imbued was distasteful to him. He, however, accepted it, believing probably that in practice the Representative Meeting would as a general rule act in the sense its title connoted. His election to be Treasurer was something of a trial of strength: the Council had put forward another candidate, but Rayner was successful.

His term of office as Treasurer was not free from anxieties; the Association had sunk a large sum in its new buildings, and was subsequently called upon to meet serious expenditure in connexion with the discussion of the National Insurance Bill and the proposals for its amendment. He resisted a proposal to incur a permanent debt by the issue of debentures, believing that the Association would be able to meet all liabilities within a reasonable time by the judicious management of its income. In this he proved to be right, and with the able assistance of the late Mr. Guy Elliston so managed matters that when he laid down his office the finances of the Association were in a sound position. He gave a great deal of thought and time to the work of Treasurer, was acquainted with every detail, and seemed to be almost as much in London as Stockport.

Dr. Rayner was a man of quiet demeanour and, outwardly at least, of tranquil temperament. He was shrewd and kindly, ready to sympathize with a friend in trouble and to help if possible. He had his own share of sorrows and bore them with quiet courage. As a member of the Council of the Association his fellow councillors learnt to place great reliance on his judgement, never willingly given without full consideration.

He retired from Stockport eighteen months ago and went to reside at Woking; there he died and was buried at Frensham, near by, on the afternoon of January 21st. The British Medical Association was represented at the funeral by Dr. Alfred Cox. At the same hour a memorial service was held at St. Mary's Parish Church, Stockport. It was attended by representatives of the borough and county magistrates, of the Stockport Infirmary, of the Stockport Medical Society, and of the many local institutions with which Dr. Rayner had been connected, and by the Mayor and other members of the Stockport Town Council.

Dr. Rayner married in 1870 Miss Hartree of London, by whom and by two sons and four daughters he is survived.

We are indebted to Sir JENNER VERRALL for the following tribute to the memory of Dr. Rayner, with whom he worked on the Council for many years:

Though there are, one will hope, many members thoroughly conversant with the work of Dr. Rayner on behalf of the Association, may I be allowed from an intimate knowledge of the way in which the work was done, to add my testimony to his great worth? As Treasurer his most important help was given, and this at very difficult and anxious times. For a long period we were indebted to him for sound advice on financial matters; it was a great pleasure to Dr. Rayner that the position of the Association in this respect had been much improved during his tenure of office. But out of my memory of many years' association with him I would speak of his geniality and charm of manner, his goodness of heart, and abundant sympathy. This he carried with him in working hours and, when work was over, he was an excellent friend and companion. I have never met anyone who so convinced you that hospitality and friendly intercourse were a joy to him. So long as his health and strength remained he grudged no labour, no thought in our service, and we who loved and trusted him will assuredly keep his memory green.

Dr. ALFRED COX, Medical Secretary of the Association, writes:

Dr. Rayner belonged to that honoured band of men who are prepared to do anything for the British Medical Association, and fate so ordained it that he was placed in a position to prove his devotion. With an excellent practice and an assured local position he found himself able to give as much time to our central work as is expected from a Treasurer—and that means a great deal. I had met him on some of the committees of the Association beforehand, but my first real

acquaintance with him began in August, 1907, when, at the Annual Meeting at Exeter, Sir Victor Horsley moved and I seconded his election as Treasurer. There was a sharp contest, in which Dr. Rayner represented those who earnestly believed in the then new constitution of the Association, while his opponent, Mr. C. R. Straton of Wilton, a highly esteemed member of the Council, was regarded as representing the more conservative views. After the election Dr. Rayner said that he had been a member of the Association for some thirty years and had taken a great interest in the work both of his own Branch and that of the Association generally; he hoped that at the end of his term of office, if he lived for the three years, they would say he had done his work as well as those who had preceded him. He lived not only to have this said of him, but to make a record, for he held the office for nine years, resigning in 1916. In that year he was elected by the Representative Meeting as a whole as one of the four members of Council chosen by it, and finally retired from the Council in 1917. In 1914 he was awarded the Gold Medal of the Association, and the Chairman of Council (Dr. Macdonald), in presenting it, told the meeting what an anxious post that of Treasurer had been for the past few years, and referred to the "distinguished bravery" Dr. Rayner had shown in administering the finances of the Association during a critical period. The term was not an exaggeration.

I came on the Central Staff in 1908, and then saw a great deal of Dr. Rayner, though, of course, as Treasurer he came much more in contact with my deceased colleague Mr. Guy Ellistou. A Treasurer, however, is *ex officio* a member of all committees, and Dr. Rayner did his full share of committee work. The impression mainly left on my mind by him was his cheery optimism. He was as good as a sunny day coming into the office. We went through some most anxious times during his term as Treasurer, but I never saw him down-hearted. His faith in the future of the Association was unassailable. The most striking evidence of this was the occasion on which, when the funds of the Association were heavily overdrawn by the demands made on us by the Insurance Act fight and the bankers were getting restive, he offered to place (and I believe did place) his own private account at the service of the Association. He was a very hospitable man and nothing gave him greater pleasure than to collect a few of his fellow workers together, as he frequently did at the National Liberal Club, and give them a good dinner. He enjoyed such a function thoroughly, and he saw that all his guests did too. Another thing which could not fail to strike anyone brought closely into contact with him was his pride in his profession, in his own practice, and in his own town. I never knew a man who was prouder of his position as a general practitioner than Dr. Rayner was. He regarded his patients as part of his family and was ready to put himself to any amount of inconvenience for any of them. As I look at his photograph which hangs in my office I feel devoutly thankful for the privilege of having worked with a man like Dr. Rayner and for an Association which can attract and command the devotion of such men.

DR. JAMES LAWRENCE, late of Darlington, died at the close of last year at Westward Ho, North Devon, whither he had retired some two years ago. Born in 1844, near Portrush, he received his medical education at Belfast and Dublin, graduating M.D., M.Ch., R.U.I. in 1871, and taking the M.R.C.S. Eng. diploma in 1872. In the latter year he went to Darlington Hospital as house-surgeon, and in 1874 he was appointed medical superintendent to the Infectious Diseases Hospital, becoming medical officer of health in 1882. He supervised the building of the Darlington Fever Hospital on its present site, and worked hard and successfully to improve the sanitary conditions of the town. He had also an extensive private practice, and was for many years senior surgeon to the Darlington General Hospital. He was held in the highest affection and esteem by all who knew him, and his fellow practitioners marked their appreciation, personally and professionally, by making him a handsome presentation on his retirement from the office of medical officer of health in 1911. Dr. Lawrence was keenly interested in many branches of sport; he had been a well known dartsman, and he was a director of the Darlington Football Club. He was an old member of the British Medical Association, and at the last meeting of the Darlington Division a resolution of condolence was unanimously passed, many tributes being paid by the members present to the memory of Dr. Lawrence. He leaves a widow and five children.

VITAL STATISTICS FOR ENGLAND AND WALES, 1921.

We are indebted to the Registrar-General for the following statement regarding the birth rates and death rates and the rates of infantile mortality in England and Wales and certain parts of the country during 1921.

ENGLAND AND WALES.

Birth Rate, Death Rate, and Infant Mortality during the Year 1921 (Provisional Figures).

	Birth Rate per 1,000 Total Population.	Death Rate per 1,000 Population (Crude Rate).	Deaths Under One Year per 1,000 Births.
England and Wales	22.4	12.1	83
95 great towns, including London (populations exceeding 50,000 at the Census of 1911)	23.5	12.3	87
148 smaller towns (populations from 20,000 to 50,000 at the Census of 1911)	22.7	11.3	84
London	22.8	12.4	79

The death rate for England and Wales relates to the whole population, but that for London and the groups of towns to the civilian population only.

The death rate for England and Wales is the lowest on record for the country as a whole, and the infant mortality is the lowest on record with the exception of the rate in 1920. The birth rate is the lowest recorded for the whole country except in the war years 1915-1919.

The Services.

SANATORIUM TREATMENT FOR TUBERCULOUS OFFICERS.

AN Army Council Instruction (No. 15 of 1922) provides that as from January 1st of this year the cost of sanatorium treatment for officers and nurses on full or half pay who are suffering from tuberculosis, and whose disabilities have been contracted in and by military service, may be refunded up to a limit of 8 guineas a week. Officers and nurses whose disabilities have not been directly contracted in and by military service, but have only been aggravated by such service, will cease from the same date to be eligible for such sanatorium grants. This Instruction cancels Army Council Instruction 339 of 1919.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on January 20th the following medical degrees were conferred:—

M.D.—Sir William T. Lister.

M.B., B.Ch.—R. L. Williams.

B.Ch.—D. Crawford, G. F. Abercrombie, W. R. Carling, *C. Dunscombe.

* Admitted by proxy.

UNIVERSITY OF ST. ANDREWS.

At the Graduation Ceremony held on January 20th the following were among the degrees conferred:

M.B., Ch.B.—T. K. Buchanan, Phyllis Fleming, Nona S. Lesslie, Katharine D. Macfarlane, J. N. D. Smith, Margaret H. R. Young.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Hunterian Lectures.—Mr. Kenneth M. Walker will deliver a Hunterian lecture on the nature and cause of old age enlargement of the prostate in the theatre of the Royal College of Surgeons, Lincoln's Inn Fields, W.C., on Friday, February 3rd, at 5 p.m. Mr. Alan H. Todd will deliver a Hunterian lecture on orthopaedic aspects of rheumatoid arthritis on Monday, February 6th, at 5 p.m.

THE provisional figures of deaths in the great towns registered in the week ending January 21st show a considerable decrease in London, where 443 deaths from influenza are returned, as compared with 551 in the previous week. The total for the 105 great towns has increased from 1,262 to 1,433. The most noteworthy increases are in the northern and midland cities, especially Newcastle-on-Tyne, 82 against 23 in the previous week, Gateshead 42 (13), Sunderland 40 (6). In the south, Brighton, Bristol and Portsmouth record increases. One-third of the deaths from influenza in London are of persons over 65.

Medical News.

THE first of Sir Leonard Rogers's three Lettsomian Lectures on amoebic liver abscess will be given before the Medical Society of London on Monday, January 30th, at 9 p.m. This lecture will deal with etiology and pathology. In his second lecture on Wednesday, February 8th, Sir Leonard Rogers will consider the varieties and treatment; and in the third lecture on Monday, February 20th, he will discuss prevention and the recent reduction in prevalence and mortality.

A THREE weeks' course of post-graduate study for general practitioners will be given, under the direction of Sir James Mackenzie, at the St. Andrews Institute for Clinical Research, commencing on May 3rd. The course will consist of lecture demonstrations dealing with the symptomatology of disease in its early stages, and will be supplemented by demonstrations on matters of clinical interest in anatomy, physiology, chemistry, bacteriology, ophthalmology, and radiology. The fee is 10 guineas. Early application should be made to the Secretary, the Clinical Institute, St. Andrews, for particulars and advice with regard to securing rooms.

SIX lectures on the physiology and pathology of ante-natal and early post-natal life will be given by Dr. W. M. Feldman at the Infants' Hospital, Vincent Square, Westminster, S.W., on Thursdays, at 4 p.m., commencing on February 2nd. Members of the profession are invited to attend.

A FUND for a wedding present to Princess Mary has been opened by the Lord Mayor of Manchester and the Mayor of Salford. It is hoped to raise one million shillings (£50,000) between Manchester and Salford, and the object to which this sum is to be devoted is the District Nursing Association. The income will be used to add another fifteen nurses to the fifty-three at present working among the sick poor of Manchester and Salford, and it is proposed to call them Princess Mary nurses.

A FURTHER course of lectures and practical instruction for the Diploma in Psychological Medicine, granted by several universities, will be held at the Bethlem Royal Hospital, London, commencing at the end of this month. Lectures will be given by members of the staff of the Bethlem Royal Hospital and others, including Dr. Kiuner Wilson, Dr. William Brown, Sir Maurice Craig, Dr. M. H. Smith, Dr. J. A. Hadfield, Dr. James Collier, and Dr. C. Staudford Read.

A RECTOR's telegram announces that Sir Arthur Currie, principal of McGill University, has received the following intimation from Lord Atholstan, the Canadian newspaper proprietor, better known in this country as Sir Hugh Graham, LL.D. *honoris causa* of the University of Glasgow: "To help in stimulating the work of research throughout the world I hereby offer a prize of 100,000 dollars to the graduate or student of any recognized university who within five years after this date is the first to discover a medicinal treatment for the effective cure of cancer, the decision to be left to the Royal Colleges of Physicians and Surgeons, London, England. This offer may be renewed."

THE Voluntary Hospitals Commission has had under consideration the preparation of a simplified uniform system of accounts which could be recommended for adoption by hospitals to which the uniform system of King Edward's Fund may be inapplicable. The Commission has appointed a small subcommittee to draft proposals for this purpose, and has secured the assistance of Captain H. G. Howitt, D.S.O., of Messrs. W. B. Peat and Co., who was closely associated with the preparation of the financial statements for Lord Cave's Committee on the Voluntary Hospitals.

A CONGRESS of medical education, licensing, public health, and hospitals will be held in Chicago from March 6th to 10th. The congress will include representatives of the Council on Medical Education and Hospitals and the Council of Public Instruction of the American Medical Association, the Association of American Medical Colleges, the Federation of State Medical Boards of the United States, and the American Conference on Hospital Service.

THE last issue of the *St. Dunstan's Review*, which is published monthly as a record of St. Dunstan's men all over the world, is a special memorial number commemorating the life and work of the late Sir Arthur Pearson, whose tragic death all interested in the welfare of the blind so greatly deplore. Included with the account of the funeral and details of Sir Arthur Pearson's fascinating career are a number of personal memoirs and tributes, which were paid to his memory from all over the world. The work to which he was so devoted is being carried on unflinchingly, and, as we have already announced, a memorial fund has been initiated to consolidate and endow all the charities for the blind in which Sir Arthur Pearson was interested.

DR. J. GORDON THOMSON, lecturer on protozoology at the London School of Tropical Medicine, has, at the invitation of the British South Africa Company, gone to Rhodesia to investigate protozoological diseases in Rhodesia. Dr. Thomson, who sailed on January 5th, expects to be absent six months, and will give special attention to the etiology of blackwater fever.

A CONFERENCE of experts is in session at the Ministry of Health, under the chairmanship of Mr. I. G. Gibson, C.B.E., Assistant Secretary to the Ministry, to consider what measures can be taken in view of the shortage of water which now exists, and is thought not unlikely to increase in the near future. The members are Sir Alexander Houston, M.D., Metropolitan Water Board; Dr. W. H. Bullough, M.O.H. for Essex; Dr. W. H. Hill, M.O.H. South Oxfordshire Combined Districts; Mr. R. Ross, Public Analyst, Burnley; Mr. F. W. Davies, Waterworks Engineer, Nottingham; with Dr. S. W. Wheaton, Medical Officer, Mr. E. A. Sandford-Fawcett, Chief Engineer, and Mr. R. J. Simpson, a principal of the Ministry.

THE annual general meeting of the Society of Superintendents of Tuberculosis Institutions will be held at 122, Harley Street, on Monday, January 30th, at 4 p.m.

THE annual report of Livingstone College, Leyton, for 1920-21 states that during the year the lectures and clinical work at the college were opened to women students, of whom five attended during the whole or part of the session. The college was founded in honour of Dr. Livingstone in order to provide practical training in medicine, surgery, and tropical hygiene for missionaries who expect to work in fields where qualified medical aid is not available. The value of such partial training, though it is, of course, no substitute for the medical curriculum, is considerable, and at the last Commemoration Day Sir George Makins said that such instruction as the students received would make them capable of doing an amount of good impossible without it. The number of students attending the courses showed a slight increase on the previous year, although the numbers are not yet up to pre-war entries. The financial state of the college shows an increased deficit, and the committee urges those interested in the work to do all in their power to raise the £1,500 to £2,000 needed to balance the accounts.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Athology, Westrand, London*; telephone, 2630, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*, telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Mediscera, Westrand, London*, telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 15, South Frederick Street, Dublin (telegrams: *Baculus, Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4361, Central).

QUERIES AND ANSWERS.

MENTAL DEFECTIVES.

"D. C. D." describes a case of mental deficiency with vicious tendencies in a boy, aged 15, and asks to be recommended a special school.

The case is possibly certifiable under the Mental Deficiency Act, 1913. In this event the course "D. C. D." can be advised to take depends upon the financial position of the parents or guardians.

(1) If not moderately well off the case should be referred to the county authorities. Each county council has a special Mental Deficiency Committee for the administration of the Act, and

application should be made to the clerk to the Mental Deficiency Committee at the county or town hall belonging to the area in which the boy is resident. The necessary steps will then be taken to have the case sent to a home, if it should prove to be mentally deficient.

(2) If the parents are in a position to make the boy a private patient in some certified institution, application should be made for his admission to one or other of the various homes in the country. The institutions which may be suggested are the Royal Albert Institution, Lancaster, or the Royal Earlswood Institution, Redhill, Surrey (Secretary, Mr. H. Howard, 14-16, Ludgate Hill, London, E.C.). The diagnosis of these cases is often very difficult, and possibly it would be well to seek expert opinion and advice.

Miss Evelyn Fox, Secretary of the National Association for the Feeble-Minded, 296, Vauxhall Bridge Road, Westminster, London, S.W., would probably be helpful and be in a position to give all particulars as to various institutions.

INCOME TAX.

"R.A.M.C." writes: (1) Can I claim an assessment on the three years' average if two of them were spent as a captain R.A.M.C. and the third as an assistant? (2) I received a bonus as assistant on April 10th, 1921, for the previous fourteen months; in which year does this fall?

It is assumed that "R.A.M.C." is still an assistant.

(1) Yes—not as a legal right, but on the strength of the concession semi-publicly announced by the Board of Inland Revenue; (2) the bonus should be regarded as spread over the period for which it was paid; the accident or incident that the actual payment was postponed is not material.

"IKONA" (to whom a reply was given on December 10th, 1921, p. 1015) writes to explain that though he has pressed for the allowance of expenses, his claim has not been allowed, and the collector is still demanding payment of the full amount of tax charged.

As our correspondent has given notice of appeal (presumably within the statutory time limit), the collector has no right to apply for the tax, and certainly no claim to payment unless the appeal has been heard. We advise "Ikona" to write to the inspector pointing this out, and requesting him to arrange for the collector's application to be withdrawn until the appeal is settled; he might further say that he cannot conveniently call on the inspector, and would be glad if the latter will state in writing his objections to the claims made.

LETTERS, NOTES, ETC.

THE Librarian of the British Medical Association wishes to replace a copy of Dr. Batty Shaw's book *Organotherapy*, which has been lost, and cannot be supplied by the publisher as it is out of print. The Librarian is prepared to pay the publishing price, 6s., for a copy of the book.

FLAT-FEET AND TOE TROUBLES.

DR. CHAS. J. HILL AITKEN (Kilnhurst, near Rotherham) writes: About four months ago a man of 45 asked me to look at his great toes. The right was extremely tender on pressing on the nail, and the left looked as though the ulcer of an ingrowing toe-nail would shortly appear. I had read an article in the *Practitioner* by Dr. Robert Hutchison on flat-feet, and took the trouble to examine the patients' insteps. It seemed to me they were inclined to bulge downwards as he stood. With the idea that when one part of a mechanical device gets out of order the mischief may show in other parts, I suggested that his flat arches were really the cause of his painful toes. He differed from me, and decided to buy bigger boots. He did, but returned to me in a week limping. He then acted on my advice, and bought a pair of instep supports. With these he found he could get about comfortably in any boots, new or old, big or proper fitting. I saw him the other day, and he told me his left toe bothered him not at all, and his right only a little. He was wearing the boots he originally blamed for his trouble—block toes.

HANGNAILS.

DR. CHAS. J. HILL AITKEN, M.D. (Kilnhurst, nr. Rotherham) writes: I have looked in two well-known books on skin diseases, and find no reference to hangnails. The following facts were told me by a layman who used to be much bothered by these unsightly and potentially dangerous lesions. Various popular preventives had proved useless, and my profession had availed him nothing. A nervous person, he discovered he would unconsciously fiddle with his nails and so start a hangnail. He broke himself of this habit and had no hangnails. He then had a series, and discovered he was wounding himself when using the wooden matches to light his cigarette. The sharp edge of the cover was the agent. He eliminated this cause by using care in opening the box. He then had another series, and usually in the right hand. He discovered the cause to be a suit of hard cloth which he was wearing. The breast pocket was small, and

his spectacle case was a tight fit. He was wounding his fingers when he thrust the case into the pocket. By acting on the result of his own observations he freed himself from hangnails, which had been the bane of his life for years.

HERPES AND VARICELLA.

DR. LEONARD ABRAHAMSON (Dublin) writes: In view of the recent discussions on the relationship between varicella and herpes zoster, I deem it of value to publish the following experience: Some time ago I was called upon to treat a boy suffering from chicken-pox. After he had recovered his little sister fell ill with the same complaint. A week after the girl had got well, two members of the household—the mother and a maid—developed attacks of typical herpes zoster.

MOTOR CARS: SPARE PARTS.

DR. J. WILFRED GEORGE (Lawder, Berwickshire) writes: The dynamo of my Standard two-seater became faulty after five months' use. I wrote to the company and asked if they would give me a dynamo on loan while mine was being repaired. They sent a new one by return. I fitted it and returned the old one. They now have written that the defective dynamo has been repaired, but since the new one I got is absolutely perfect and gives me complete satisfaction, they wish me to keep it, and they make no charge in the matter whatever. Such exceptionally kind and generous treatment of "Standard" owners deserves mention in a paper whose readers are so dependent on cars. Let me further add the car is very good indeed in every respect. I have no interest in the company in any way except that of a satisfied and grateful user.

MOTOR INSURANCE.

"F. D. B." (London, S.W.) writes: I should like to draw the attention of fellow members with cars to the advantage gained by insuring through the Medical Insurance Agency (c.o. the British Medical Association, 429, Strand, London, W.C.). I paid £16 17s. on Lloyd's M.P. Policy, and out of curiosity filled in a paper for a quotation from the Medical Insurance Agency, which was £15 3s. 4d. for identically the same thing. As the benefits accruing from this source are all devoted to medical charities, whose resources are so strained at present, members by taking advantage of this Agency would be benefiting not only themselves but the less fortunate members of the profession.

WOOLLEN WINDING SHEETS.

DR. C. M. DAVIDSON (Rusington, Sleaford, Lincoln) writes: This is a copy of an affidavit sworn April 8th, 1733, at our local church:

"Mary T— made oath that the body of Widow Rogers was not wrapt up or wound up in anything but which was made of sheep's wool according to an Act of Parliament in that case provided.

(Signed) A. S.,
Curate."

On turning up the deaths I find that from April 8th to May 9th there were seven deaths out of a total of ten for that year, two being in the same house on one day. Evidently an epidemic. In 1729 (four years previously) there was evidently a similar epidemic in April and May, there being seventeen deaths at this time out of a total of twenty-four for the year, several being in the same house. It would be interesting to find out the Act mentioned and the reasons for this particular method of burial being used.

Among the expedients resorted to for stimulating the demand for woollen goods in Stuart times was an Act passed in the reign of Charles II, decreeing that all dead bodies should be buried in woollen shrouds. This remained on the Statute Book for 120 years.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 29, 32, 33 and 34 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 30 and 31.

THE following vacant appointments of certifying factory surgeons are announced: Aberdeen (Aberdeen), Long Sutton (Lincoln), Manchester, West Central (Lancs), Reading (Berks).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 423, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a cheque or postal note for the full amount.

NOTE.—Advertisements should be marked with the initials or numbers of the Post Office to receive posts.

MEDICINE.

74. Treatment of Pulmonary Tuberculosis.

CH. MANTOUX (*Journ. de Méd. et de Chir.*, December 10th, 1921) states that the treatment of pulmonary tuberculosis is of two kinds—systematic and symptomatic. *Systematic*.—The following are considered: Salts of lime, cod-liver oil, arsenic, tannin, iodine, and creosote. (1) Lime. A glass of Pougues or Saint-Galmier water to be taken an hour before meals, a glass and a half at meal times, and at the meals a cachet of carbonate of lime 0.30 gram, tricalcium phosphate 0.50 gram, sodium chloride 0.15 gram, and calcined magesia 0.10 gram. Adreualine (20 drops of a 1 in 1,000 solution per diem) is frequently added. The treatment leads sometimes to constipation. It ought to be used for a long period. (2) Cod-liver oil. This should only be given in winter; 50 grams should be given at least every day. (3) Arsenic is indicated in weak, anemic, and thin patients. It is not suited to plethoric people. It can be given by the mouth as sodium arsenate, Fowler's solution, arrhenal, or as Bonrbonle water. Arrhenal and Fowler's solution can be given by the rectum, 2 to 15 drops in a little tepid water, and arrhenal or sodium cacodylate subcutaneously. (4) Tannin. This drug assists in decreasing congestion, but sometimes causes focal reactions and discharge of caseous matter. It is best given in solution at the end of meals, either in alcohol or extract of walnut leaves. (5) Iodine is especially indicated in scrofulous conditions; it produces liquefaction of the bronchial exudates, and is to be recommended in fibrinous and in emphysematous tuberculosis. It should be proscribed at times of exacerbation owing to the congestive conditions it is apt to provoke. One of the best ways of giving it is as syrup of iodine and tannin. (6) Creosote is the drug of choice in the bronchitic forms. It is apt to produce exacerbations and must be given with care. It is best given as pure beechwood creosote by the rectum 10 grams, decoction of wood of Pauaua 90 grams, as an emulsion. It can be used subcutaneously as oil of creosote. Guaiacol and thioeol are inferior to creosote. *Symptomatic*.—Fever: This often yields to prolonged rest. The question of antipyretics is not determined by the height of the fever, but by the amount of constitutional disturbance present, especially the presence of marked anorexia. Acid camphorate of pyrimidon 0.25 gram in a cachet, two to three a day, or 0.25 gram of eryogenine are the best drugs. Asthenia: Strychnine, or camphorated oil are excellent remedies, the latter in doses of 1 to 4 c.cm. a day (10 to 20 per cent. solution). Cough: Codeine phosphate, diodon, heroin, are all valuable, but should not be given unless absolutely necessary. Abundant expectoration indicates the use of creosote and its derivatives, and inhalations of balsams. Night sweats generally yield to hygienic treatment, but if not, alcoholic tincture of sage, 30 to 50 drops, should be tried, or agaricin; atropine should only be used as a last resort. Marked anorexia may be alleviated by subcutaneous injection of oil of camphor, but the best remedy of all is morphia and its derivatives.

75. MARAGLIANO (*Rif. Med.*, November 5th, 1921), speaking at the recent Medical Congress in Naples, says that the tubercle bacillus injures the organism by reason of poisons secreted by it or contained in its protoplasm, and the defence put up by the body consists in the formation of antibodies and ferments. The tubercle bacillus alone is not sufficient—a suitable soil is necessary, so that the presence of the bacillus does not necessarily mean tuberculosis. Since we know more to-day about antibodies and immunity, it is possible to induce immunity to tubercle by means of suitable vaccines. The development of tubercle means that the defensive forces of the organisms have been overcome. Immunity may be acquired automatically with a spontaneous infection, but it is possible to confer it artificially. Specific therapy may be active or passive—if active, tuberculous antigens are given with a view to provoke in the body antibodies; in the passive therapy defensive materials dissolved in the blood are used. The author claims many successes in his preventive vaccination treatment, and says it ought to be used in all tuberculous families.

76. Tuberculous Myocarditis.

MASSINI (*Schweiz. med. Woch.*, December 15th, 1921) elaborates the argument that many diseases, such as granular kidney, may be tuberculous—that is, be traceable to the direct

action of the tubercle bacillus, even though the microscopic structure of the tissues involved does not tally with that commonly associated with tuberculosis. In support of this view he records the case of a woman of 68 who suffered from chronic myocarditis, the diagnosis of which was confirmed by necropsy. This revealed no specific tuberculous changes in any organ, but inoculation of guinea-pigs with the muscle of the heart resulted in typical tuberculosis, and the tubercle bacilli cultivated from these guinea-pigs conformed to the human type. The author suggests that such tuberculous disease of the myocardium may be comparatively common, and that the immunity to frank tuberculosis shown by some subjects of heart disease may simply be the immunity conferred by a mild or abortive and (in the present state of knowledge) apparently atypical form of tuberculosis.

77. Intravenous Injection of Calcium Chloride in Pulmonary Tuberculosis.

MAENDL (*Zeit. f. Tuberk.*, November, 1921) has treated 250 cases of pulmonary tuberculosis by intravenous injections of calcium chloride. In haemoptysis of a severe degree 5 c.cm. of a 10 per cent. solution were given at intervals of eight hours until the haemorrhage ceased. Maendl has also given the injections prophylactically at intervals in patients who have a tendency to haemoptysis. In such cases he recommends courses of twenty injections, which are given daily or every two days, with a fortnight's interval between each course. In a number of patients with obstinate pyrexia the temperature was reduced to normal by the injections. The treatment also had a remarkably favourable effect upon the general condition, and especially on the cough, expectoration, night sweats, and dyspnoea.

78. Sodium Cinnamate in Tuberculosis.

LAUTIER (*Bull. Soc. de Thér.*, October 12th, 1921), as the result of his investigations, came to the following conclusions: (1) Sodium cinnamate definitely increases the output of urine, the increase amounting to one-third of the normal amount of urine passed in the twenty-four hours. (2) If before treatment the urine passed is deficient in urea and rich in uric acid, urates, and phosphates, after a few days' treatment the urine shows the following changes: The urea is increased to the normal amount and the uric acid and urates are diminished in proportion to the increase in the urea; the phosphates are much diminished and their elimination tends to return to the normal level. (3) If before treatment the patient's urine is normal, it undergoes no change in the course of treatment. (4) If before treatment one of the elements in the urine is excreted below the normal amount, the amount excreted tends to return to normal under treatment. Sodium cinnamate is thus a mild diuretic and a regulator of the metabolism of nitrogenous substances and phosphates in the tuberculous organism. The gain in weight shown by the patient is mainly due to this action.

79. Treatment of Pulmonary Gangrene.

LEMIERRE, KINDBERG and PIÉDELÉVRE (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, November 24th, 1921) remark that several new methods have been introduced into the therapeutics of pulmonary gangrene during the last few years, such as artificial pneumothorax (F. E. Weil), an anti-gangrene serum (Dufour, Scmelaigne and Ravina, Rathery and Bordet, Honzel and Sevestre, Netter), arsenobenzol (Perrin, Dumstresen, Maute, Pujol), and tincture of garlic (Loeper, Forestier and Hurrier). The present writers record a case of pulmonary gangrene in a man aged 43, which was successfully treated by subcutaneous injections of 40 c.cm. of an anti-gangrene serum (20 c.cm. of anti-perfringens serum, 10 c.cm. of anti-oedematis serum, and 10 c.cm. of anti-vibrio septique serum), repeated daily for six days, followed by tincture of garlic in doses of 20 drops at first, later increased to 50 drops a day.

80. Bronchotetany.

ACCORDING TO MOSCHINI (*Il Policlinico*, Sez. Prat., November 28th, 1921), who reviews the literature and records three personal cases in children aged 6 months, 10 months, and 1 year, many respiratory affections occur in infancy presenting the symptoms of bronchopneumonia, capillary bronchitis or bronchial asthma, although the anatomical changes in the pulmonary tissue typical of these diseases are absent, the condition being due to spasmodia, and the anatomical substratum being a spasm of the bronchial

muscles. These cases, to which Lederer in 1913 gave the name of "bronehotetany," should be regarded as examples of spasmophilia just as much as cases of tetany, laryngospasm, and infantile eclampsia. The differential diagnosis of bronehotetany is based chiefly on the coexistence of obvious or latent spasmophilia. This diagnosis is of considerable practical importance, because the continuance or increase of a diet of cow's milk aggravates the disease, whereas the symptoms are improved or completely cured by suppression of the milk.

81.

Relapses in Pneumonia.

SACQUÉPÉE (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, November 17th, 1921), who records an illustrative case, states that a study of the literature shows that successive attacks of pneumonia in the same patient are usually due to the same strain of pneumococcus, although this rule is liable to exception. In two cases reported by Henry Thomas, in which the second attack occurred three months and a year respectively after the first, Type I pneumococcus was present in both attacks. In another case reported by Thomas the first attack was due to Type II and the second to Type I. A fourth case showed Type IV at the time of the first attack, and an atypical Type II in the second attack. The most curious case is that of R. Cole, whose patient had sixteen attacks of pneumonia. A bacteriological examination was not made until the twelfth attack, in 1916, which was due to Type I. The same year he had a thirteenth attack due to Type III, a fourteenth due to Type IV, and a fifteenth due to Type III. In the sixteenth attack, which occurred in 1917, Type III was again found. The patient was treated with a vaccine for Type III after the fifteenth and sixteenth attacks, and from February, 1917, to January, 1921, no further attacks occurred. Sacquépée's patient in his first attack had pneumonia of both bases, which was treated with serum, and was followed by empyema. When the discharge had nearly dried up, pneumonia of the left apex developed, which was treated with serum, and cleared up in a few days. At the time of the first attack two different pneumococci were found, the first being Type I and the second atypical. The empyema was due to the atypical pneumococcus, and the second attack to Type I. The action of the pneumococcus serum was moderate in the first attack, nil in the empyema, and vigorous in the second attack.

SURGERY.

82.

Pneumoperitoneum.

PROUST (*Bull. et Mém. de la Soc. de Chir. de Paris*, December 20th, 1921) describes the modifications that have been adopted in the technique of this valuable means of diagnosis. The patient must have his bowels cleared out the night before, and have nothing to eat the day of the examination. An injection of morphine is usually given. The inflation should not be given directly from the gas cylinder, but through some form of apparatus such as that used to produce artificial pneumothorax. The peritoneum is punctured with a trocar and the inflation controlled by means of a manometer, which oscillates with the respiratory movements and shows the gas is entering the peritoneal cavity. The inflation is made slowly and under low pressure. The amount of gas injected should be about two litres and should cause no pain. A mixture of oxygen and carbonic acid gas is found best, and is absorbed a few hours after the examination. Owing to its lightness the gas tends to rise, while the abdominal organs are affected by gravity and the different positions of the patient. The kidney outline is well seen, and in a case of tumour of the left kidney, to differentiate it from the spleen, it is necessary to turn the patient under the screen into different positions. The outline of the liver is particularly well shown, and the gall bladder in perhaps half the cases examined. The shape of the spleen is clearly seen, and if it is difficult to separate from the kidney, the patient is turned as already stated. To examine the pelvic organs the patient must be placed in the Trendelenburg or genu-pectoral position, and the broad ligaments, tubes, and ovaries can be clearly demonstrated. After pneumoperitoneum the patient must remain in bed for forty-eight hours. It is contra-indicated in the cachectic, the anaemic, and in those with cardiac or respiratory disease, and also, of course, in acute abdominal conditions.

83.

The Treatment of Congenital Club-foot.

FISKE (*Journ. Orthopaed. Surg.*, December, 1921) points out that the important factors in the treatment of congenital club-foot are the proper selection of treatment and the persistency with which it is carried out. The two methods

largely in use at the present time are the corrective operation and the essentially non-operative manipulative treatment. Most orthopaedists agree that treatment should be begun in the first month of life, and this consists in manipulative treatment followed by fixation in plaster-of-Paris; up to the age of six months operation or anaesthesia is not advised. In a case of congenital equino-varus correction of the deformity permits of no postponement. The soft elastic tissues of the foot are most favourable for correction, and early reshaping can be readily effected. If the foot grows straight during the first year, it will stay straight. The treatment at this stage, therefore, consists of alternate manual correction and fixation in plaster. Cases seen at a later period, up to 2 years, and when conservative treatment fails, may require tenotomy and forcible correction. But the slower manipulative method, without causing damage to the structures of the foot, favours ultimate restoration of normal function. Later, if conservative treatment has failed, more extensive operations may be necessary, such as cuneiform tarsectomy. After full over-correction has been obtained the brace is almost universally used for the retention of the foot in this position. The aim of treatment must be to reactivate the overstretched muscles and ligaments until they outbalance their previously contracted opponents. By this means the active factors in relapse will be rendered permanently ineffective. This is the essence of the conservative, functional treatment.

84.

Massive Hypertrophy of the Breast.

A CERTAIN degree of enlargement of the breast is within physiological limits: very rarely, however, the breasts attain such dimensions as to become a nuisance to their possessor because of their unsightly appearance or the mere burden of weight. KEYSER (*Surg. Gynec. and Obstet.*, December, 1921) reviews the recorded cases on this subject and gives notes of 4 cases occurring in the Mayo clinic. The age of onset is usually under eighteen years, and the patient may, after the first catamenia, notice an enlargement of the breasts so great as to be a source of embarrassment. The process is usually bilateral, and the average duration of growth is ten months. The size of the breasts in the majority of cases is from 7 to 10 lb. The largest breasts recorded are those of Durston's patient, the left breast weighing 64 lb., the right 40 lb. The secretory activity is very variable. The normal development of the breast seems to depend on the ovary, and there is evidence which suggests that the massive hypertrophy may be etiologically related to an ovarian malfunction. A distinction must be made between true mammary hypertrophy and those excessive enlargements due to the presence of tumours. In this condition the normally differentiated tissue elements undergo hyperplasia which is diffuse throughout the organ. Pathologically they may be classified into two groups: fibro-epithelial hypertrophy, and adipose hypertrophy in which fatty tissue composes the bulk of the breast. Diagnosis is easy from the diffuse nature of the process, the bilateral enormous enlargement, rapid growth and absence of pain. The frequent association with puberty and pregnancy makes the diagnosis clear. Spontaneous regression occurs in some cases, and the best plan is to wait for a time in the hope that the breast will decrease in size. If time fails to ameliorate the condition, then amputation is indicated and apparently has no evil after-effects.

85. Gonorrhoeal Infection of Epididymis and Tunica Vaginalis.

ACCORDING to LAVENANT (*Journ. d'Urol.*, October, 1921), involvement of the epididymis and tunica vaginalis occurs in 25 to 30 per cent. of all cases of gonorrhoea, but only in those in which secondary or associated infections are very pronounced. According to Fournier's statistics, the complication is most frequent between the eleventh day and the fifth week. This is due to the fact that at the end of the acute stage the gonococcus, apart from exceptional cases, ceases to predominate, and that the virulence of other micro-organisms develops. The fluid contained in the tunica vaginalis is only feebly toxic for animals, so that the rarity of suppuration is explained by the attenuated character of the infection. Infection takes place chiefly by the epididymis, but is also conveyed by the lymphatics. Lavenant describes three forms of gonorrhoeal epididymitis: (1) A painful and febrile form with little or no effusion into the tunica vaginalis. Improvement may take place in four or five days, or the temperature fall gradually to normal, so that by the tenth day the acute stage is over; or the general symptoms may last only forty-eight hours, and be followed on the fourth day by (2) a painful form with effusion into the tunica vaginalis, without much rise of temperature. This form does not last more than a few days, but may appear as such from the first. (3) A less form, with a large pyrexial effusion. In such cases it is a long time before the effusion is absorbed and the enlargement of the epididymis diminishes in size.

85. Results of Treatment for Gonorrhoea.

MARINGER (*Journ. d'Urol.*, October, 1921) has drawn the following conclusions from the examination of 600 chronic cases of gonorrhoea. Only those cases were taken into consideration in which the patient had kept to a single form of treatment, so that there could be no doubt as to the relation of cause and effect between the treatment and the subsequent lesions observed. (1) The treatment which was followed by the highest proportion (25 per cent.) of chronic lesions was expectant treatment combined with opiates; (2) treatment by injection of the anterior urethra only after an expectant period was followed by chronic lesions in 19 per cent.; (3) treatment by injection of the anterior and posterior urethra after a period of expectant treatment was followed by chronic lesions in 11 per cent.; (4) the smallest proportion of complications (6 per cent.) was found after treatment by Janet's method; (5) strange to say, vigorous abortive treatment was followed by complications in only 10 per cent., and only 16 per cent. of untreated cases became chronic; (6) results obtained by Demouche's vaccine were superior to those obtained by other vaccines, but were less favourable in acute than in chronic cases.

87. Treatment of Gonococcal Arthritis by Intramuscular Injections of Synovial Fluid.

BALLENGER and ELDER (*Surg., Gynec., and Obstet.*, November, 1921) report successful results in 27 cases of gonorrhoeal arthritis treated by injections into the gluteal muscles of 15 to 20 c.cm. of synovial fluid aspirated from the knee-joint. The injections were repeated at about two days' interval as long as there was any fluid to be injected, but in most cases the effusion had disappeared by the tenth day. The authors have not employed vaccine or other adjuvant methods of treatment, which they believed to be unnecessary. They have also had equally successful results in cases of gonorrhoeal epididymitis, urethritis, and vesiculitis complicated by acute inflammatory effusion into the tunica vaginalis; injection of the fluid obtained by tapping appeared to lead to notably rapid disappearance of the morbid symptoms. Having cognizance of good results obtained by similar methods of treatment in acute traumatic synovitis, the authors refrain from ascribing their therapeutic results to injection of antitoxic and antibacterial substances in the fluids. Among the cases they record is that of a man, aged 47, who had healed tuberculosis of the hip, genito-urinary tuberculosis, and tuberculosis of the larynx; tubercle bacilli were found in the sputum and in the urine. After repeated injections of the fluid obtained by tapping a hydrocele which complicated an acute epididymitis, the patient gained in weight, the secretions became free from tubercle bacilli, and, after a convalescence complicated by drainage of a pyonephrotic abscess, his health appeared to be completely restored.

OBSTETRICS AND GYNAECOLOGY.**88. Partial Symphysiotomy for Pelvic Contraction.**

LOSCHI (*Zentralbl. f. Gynäk.*, October 22nd, 1921) records two cases of pelvic contraction successfully treated by partial symphysiotomy, as advocated by Costa. In this operation (see *Zentralbl. f. Gynäk.*, February, 1921) a small transverse incision is made 5 mm. below the upper border of the symphysis pubis; after reflection of periosteum and perichondrial investment, a transverse slice comprising the upper portion of the inner end of each pubic bone and the upper part of the symphysis is resected, extending from one to the other pubic tubercle, and measuring about 1 cm. from below upwards at the widest part. The advantages claimed for this operation are that it produces a lasting correction of the deformity, and that there is less danger of haemorrhage and of infection than is the case with symphysiotomy or with pubiotomy. The operation may be performed during or before labour, but preferably when the os is fully dilated; it is specially applicable in cases of moderate degrees of pelvic contraction, in which recourse is usually had to premature induction of labour. It is obvious that partial symphysiotomy finds no place in the treatment of generally contracted pelvis. Loschi claims that in cases in which the difference between the biparietal foetal diameter and the conjugate diameter of the pelvic brim does not exceed 8 or 9 mm. the operation is definitely indicated, and will permit delivery (usually spontaneous) of a living foetus. As a result of inclination of the foetal head to the side of one or other parietal bone moulding may follow, which will permit of delivery after partial symphysiotomy in cases in which the conjugate is as small as 7.5 to 7.8 cm., and in which the difference between the foetal biparietal and maternal con-

jugal measurements is as great as 16 mm. In the two cases related by Loschi the conjugate measurements were respectively 7.3 and 7.8 cm., and the biparietal foetal diameters were respectively 8 and 9.2 cm.; in both instances the child was born alive without instrumental assistance.

89. Lethargic Encephalitis and Pregnancy.

GUILLAIN and GARDIN (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, November 10th, 1921) state that the numerous articles published within the last few years on the influence of epidemic encephalitis on pregnancy show that pregnancy in such cases may be normal, or that encephalitis may be aggravated by pregnancy, or that premature delivery may occur after death of the foetus, or that abortion may have to be induced owing to the mother's life being in danger. The child in such cases may either die *in utero* or be born in a normal condition, or, on the other hand, show symptoms of encephalitis after birth. Nearly all these cases are examples of acute encephalitis which has developed in pregnancy. In only two previous cases, published by Valente and David and by Rathery and Cambassédès respectively, did the pregnancy develop in women who already presented a post-encephalitic Parkinsonian syndrome. Guillaïn and Gardin now record the case of a woman, aged 28, who became pregnant five months after the onset of lethargic encephalitis, when a Parkinsonian syndrome was already well established. Pregnancy pursued a normal course, and a healthy child was born at full term. Labour was unusually slow, and required the application of forceps. The symptoms showed no aggravation after delivery, but the woman's condition remained the same as before.

90. Venous Ligature for Puerperal Pyæmia.

ACCORDING to BIRNBAUM (*Arch. f. Gynäk.*, 1921, cxiv, 3), it is not possible definitely to state the indications for venous ligature, which, nevertheless, may be of striking therapeutic value in certain cases of slowly progressive puerperal pyæmia. Ablation (in addition to ligature) of the thrombosed vein is a useless and dangerous complication of the operation, and should not be undertaken; the same is true of hysterectomy. The author adds another to the recorded cases of cure which have followed ligature of the inferior vena cava; the operation was performed after an illness of eleven weeks, during which forty-five rigors had occurred. The vein was ligatured about 5 cm. above its point of origin; neither cyanosis nor oedema followed, and the rigors ceased immediately after the operation.

91. Ovarian Torsion.

ACCORDING to SMITH and BUTLER (*Amer. Journ. of Obstet. and Gyn.*, November, 1921), torsion of ovarian tumours during childhood is an uncommon condition, of which 26 cases only have been reported during the last twenty years. About one-half of the cases occur between the ages of 8 and 10, and in the majority the ovary only is affected. Sixty per cent. of the tumours were dermoid cysts, and the majority of cases occurred on the right side. The pre-operative diagnosis usually made is that of appendicitis, but symptoms somewhat suggestive of adnexal torsion are the presence of a tumour and the history of well-marked ladder symptoms. At any period of life torsion of adnexa which are not the site of morbid lesions is an extremely uncommon event, and fourteen cases only have been reported, of which more than half occurred before the age of 20. A large percentage of such torsions occur in close relation to the menstrual period, but three were reported during pregnancy. Either the tube or the ovary alone, or both together, may be affected. Torsion of adnexa in hernial sacs (apart from strangulation) is relatively rare; it occurs only in congenital inguinal hernias and usually in the first year of life.

92. Peritoneal Tears Produced by Myomata.

HALBAN (*Zentralbl. f. Gynäk.*, October 22nd, 1921) has been able to trace only four references to peritoneal tears consequent on rapid increase in size of uterine myomata. He relates the case of a woman, aged 36, in whom the sudden onset of right-sided abdominal pain caused a diagnosis of appendicitis to be made; a history suggesting myoma was absent, but the uterus was enlarged and tender in the region of the fundus. At laparotomy a pediculated myoma attached to the fundus uteri was found to be almost completely bereft of peritoneal investment; it was concluded that rapid growth of the tumour (which was oedematous) had caused a peritoneal tear and the appearance of the acute abdominal signs and symptoms. The author records also a case of acute abdominal haemorrhage, found at operation to proceed from a uterine myoma; a length of 2 cm. of one of the overlying veins lay free within the peritoneum without serious investment.

93. Operative Treatment of Chronic Adnexal Disease.

HOLDEN (*Amer. Journ. of Obstet. and Gynec.*, November, 1921) points out that if ovaries are to be conserved at operation and thereafter to function without causing distress it is important that an adequate circulation subsequent to operation must be assured; this is easily accomplished in the case of a normal or slightly inflamed tube, but impossible when the tube is grossly enlarged. In twelve patients the author, bearing these considerations in mind, has operated (three weeks at least after the subsidence of acute signs and symptoms) by incising unilateral or bilateral pyosalpinges along the anterior surface; the incised tubes were then suspended to the round ligaments by interrupted sutures (the raw surface being turned downwards) and the ovaries and uterini were also suspended. The patients were previously informed of the possible necessity of re-operation, which was in fact performed in at least two instances. It is claimed that the post-operative morbidity is not greater than that of other surgical treatments and that the patient is entitled to choose between, on the one hand a more radical operation which will be followed by an artificial menopause, and on the other the operation described. Eleven operations were unaccompanied by drainage: no case of the series proved fatal.

94. Radium in Cancer of the Cervix.

PIRRI (*Il Morgagni*, October 31st, 1921) reports two cases of cancer of the cervix apparently cured by radium. He refers to many other successful results after similar treatment. So far most of the cases have belonged to the inoperable class, but he suggests that many of the more serious operable cases would be much benefited by a preliminary course of radium. The scarring produced by radium does not render subsequent operation more difficult and diminishes the risk of peritoneal infection. In some cases the x rays can with advantage be associated with radium. Since radium emanations penetrate more deeply and widely than the solid, better effects may be expected from the use of them. According to Laborde most of these carcinomatous ulcers cicatrize under radium in four or five weeks: no serious amount of time is lost if subsequent operation is decided upon.

PATHOLOGY.**95. Experimental Immunity to Heat-stroke.**

IN continuation of his former work on the experimental production of heat-stroke in mice, RICHET (*C. R. Soc. Biologie*, November 26th, 1921) finds that it is possible to confer on these animals a certain degree of immunity. By exposing them to a temperature of 36° to 40° C. for about one hour, he is able to show that a state of increased tolerance to heat develops, which reaches its maximum between the twentieth and fortieth day after the exposure. Representing the resistance of the unexposed control animals as 100, then that of the treated animals may be given as 130 to 150. Whether the condition attained be one of real immunity or merely one of habituation to the effects of heat is impossible to say at present, but the fact that it is not practical to transmit this condition to other mice seems to argue rather in favour of the latter hypothesis.

96. The Serum Treatment of Tetanus

THE path of spread of tetanus toxin in the body has given rise in the past to a large amount of experimental work and a still larger amount of surmise. Chiefly based on Meyer and Ransom's work, the most generally accepted view is that it is taken up by the peripheral nerves—especially by the end plates of the motor nerves—and passes up the axis cylinders to reach the nerve cells in the anterior cornu of the spinal cord. About two years ago this theory was challenged by Teale and Embleton, who brought forward evidence to suggest that, though this mode of ascent might occur, the main path probably lay in the perineural lymphatics, by means of which the toxin gained access to the spinal cord around the anterior roots. The subject has once again been attacked by KOBAYASHI (*Kitasato Archiv. of Exper. Med.*, October, 1921), who has given his results in a long paper to which it is impossible to do justice in a summary. His work has been conducted on rabbits, with the addition of mice as testing animals. Briefly, he comes to the conclusion that the toxin is absorbed into the lymphatic spaces of the peripheral nerves. Of this a portion passes into the endoneural lymphatics and attacks the peripheral nerve fibres, while the remainder is transmitted still further centrally and attacks the spinal motor nerve cells. The actual point of attack he regards as the whole motor neurone. Having established this to his own satisfaction, he proceeded to discover the best means of introduction of antitoxin. Comparative tests of the subcutaneous, intravenous, and sub-

arachnoid routes led him to conclude that the last method was far the most satisfactory. Actually he was able to save the lives of rabbits which had already developed tetanus by giving them intrathecal injections of the antitoxin. For treatment of the disease in human beings he considers that the rational course is to administer quantities as large as possible of a highly antitoxic serum directly into the subarachnoid space.

97. Diet and Sterility.

REYNOLDS and MACOMBER (*Amer. Journ. of Obstet. and Gynec.*, October, 1921) give a preliminary report of studies of the fertility of albino rats fed on diets which were respectively deficient in the fat-soluble A vitamin, in calcium, in protein, or in both calcium and protein. The deficiencies were so small as to produce no evidence of ill health and few indications even of "poor condition"; nevertheless, each kind of deficiency led to a very definite diminution of fertility. The fertility of rats reared to maturity on a diet deficient in the fat-soluble vitamin and then mated was decreased by more than one-half. Low protein diet led to about 75 per cent. decrease in mating fertility, and diet deficient in both calcium and protein produced a still more striking variation. The authors conclude also that a slight decrease in the fertility of both partners will produce a sterile mating; that two individuals which are sterile when mated together may nevertheless reproduce freely when mated to new partners of higher fertility; and that diminished fertility sometimes results in the appearance of abortion. In connexion with the last-named finding the authors quote the observation of a patient who had had five successive abortions, and whose diet when analysed showed vitamin deficiency: a sixth pregnancy which ensued after prescription of a corrected diet led to birth at term of a living child. Examination of the ovaries and testicles of certain of the rats experimented on showed no morbid changes in animals which had received the single deficiency diets.

98. The Wassermann Reaction.

COVISA and PINEDA (*Arch. de med., cir., y espec.*, November 1st, 1921) give the following analysis of 3,000 Wassermann reactions. Among 495 cases which clinically were not syphilitic they obtained positive results in 6, or 1.21 per cent., and negative results in 489, or 98.79 per cent., 3 of the 6 positive cases being leprosy patients. Of 525 clinical y doubtful cases, 114 gave a positive reaction and 411 a negative reaction, which almost exactly corresponded to the subsequent clinical course of each case. A third group consisted of cases which were clinically syphilitic, and is subdivided by the writers into four classes. The first consisted of cases with active syphilitic manifestations for which no treatment had been employed. In 24 of these cases which were in the primary stage the Wassermann reaction was positive in 100 per cent. Of 522 cases in the secondary stage, in many of whom the chancre was not yet cicatrized, there were only 9 negative cases. Of 249 cases of tertiary syphilis, 45, or 18 per cent., were negative, and 204, or 82 per cent., positive. The remaining three groups consisted of patients who had no active manifestations of syphilis, and had had intensive, scanty, or no treatment respectively. Of 954 who had received intensive treatment, 57, or 5.97 per cent., gave a positive, and 897, or 94.03 per cent., a negative reaction. Of 216 who had had little treatment, 195, or 90.23 per cent., were positive, and only 21, or 9.72 per cent., negative; while among 15 who had had no treatment at all, 12 were positive and only 3 negative. The writers conclude that the Wassermann reaction, in addition to its great diagnostic value, possesses even greater value as a guide to treatment.

99. Clinical Reactions in the Treatment of Dermatosis by Auto-haemotherapy.
